

This copy of the TypeScript handbook was created on Tuesday, May 25, 2021 against commit <u>02613b</u> with <u>TypeScript 4.2</u>.

Table of Contents

Object Types

Conditional Types

<u>The TypeScript Handbook</u> Your first step to learn TypeScript

<u>The Basics</u> Step one in learning TypeScript: The basic types.

<u>Everyday Types</u> The language primitives.

Narrowing Understand how TypeScript uses JavaScript knowledge

to reduce the amount of type syntax in your projects.

More on Functions Learn about how Functions work in TypeScript.

How TypeScript describes the shapes of JavaScript

objects.

<u>Creating Types from Types</u>
An overview of the ways in which you can create more

types from existing types.

Generics Types which take parameters

<u>Keyof Type Operator</u>
Using the keyof operator in type contexts.

<u>Typeof Type Operator</u>
Using the typeof operator in type contexts.

<u>Indexed Access Types</u> Using Type['a'] syntax to access a subset of a type.

Create types which act like if statements in the type

system.

<u>Mapped Types</u> Generating types by re-using an existing type.

Template Literal Types

Generating mapping types which change properties via

template literal strings.

<u>Classes</u> How classes work in TypeScript

Modules How JavaScript handles communicating across file

boundaries.

The TypeScript Handbook

About this Handbook

Over 20 years after its introduction to the programming community, JavaScript is now one of the most widespread cross-platform languages ever created. Starting as a small scripting language for adding trivial interactivity to webpages, JavaScript has grown to be a language of choice for both frontend and backend applications of every size. While the size, scope, and complexity of programs written in JavaScript has grown exponentially, the ability of the JavaScript language to express the relationships between different units of code has not. Combined with JavaScript's rather peculiar runtime semantics, this mismatch between language and program complexity has made JavaScript development a difficult task to manage at scale.

The most common kinds of errors that programmers write can be described as type errors: a certain kind of value was used where a different kind of value was expected. This could be due to simple typos, a failure to understand the API surface of a library, incorrect assumptions about runtime behavior, or other errors. The goal of TypeScript is to be a static typechecker for JavaScript programs - in other words, a tool that runs before your code runs (static) and ensures that the types of the program are correct (typechecked).

If you are coming to TypeScript without a JavaScript background, with the intention of TypeScript being your first language, we recommend you first start reading the documentation on JavaScript at the Mozilla Web Docs. If you have experience in other languages, you should be able to pick up JavaScript syntax quite quickly by reading the handbook.

How is this Handbook Structured

The handbook is split into two sections:

• The Handbook

The TypeScript Handbook is intended to be a comprehensive document that explains TypeScript to everyday programmers. You can read the handbook by going from top to bottom in the left-hand navigation.

You should expect each chapter or page to provide you with a strong understanding of the given concepts. The TypeScript Handbook is not a complete language specification, but it is intended to be a comprehensive guide to all of the language's features and behaviors.

A reader who completes the walkthrough should be able to:

- Read and understand commonly-used TypeScript syntax and patterns
- Explain the effects of important compiler options
- Correctly predict type system behavior in most cases

In the interests of clarity and brevity, the main content of the Handbook will not explore every edge case or minutiae of the features being covered. You can find more details on particular concepts in the reference articles.

Reference Files

The reference section below the handbook in the navigation is built to provide a richer understanding of how a particular part of TypeScript works. You can read it top-to-bottom, but each section aims to provide a deeper explanation of a single concept - meaning there is no aim for continuity.

Non-Goals

The Handbook is also intended to be a concise document that can be comfortably read in a few hours. Certain topics won't be covered in order to keep things short.

Specifically, the Handbook does not fully introduce core JavaScript basics like functions, classes, and closures. Where appropriate, we'll include links to background reading that you can use to read up on those concepts.

The Handbook also isn't intended to be a replacement for a language specification. In some cases, edge cases or formal descriptions of behavior will be skipped in favor of high-level, easier-to-understand explanations. Instead, there are separate reference pages that more precisely and formally describe many aspects of TypeScript's behavior. The reference pages are not intended for readers unfamiliar with TypeScript, so they may use advanced terminology or reference topics you haven't read about yet.

Finally, the Handbook won't cover how TypeScript interacts with other tools, except where necessary. Topics like how to configure TypeScript with webpack, rollup, parcel, react, babel, closure, lerna, rush, bazel, preact, vue, angular, svelte, jquery, yarn, or npm are out of scope - you can find these resources elsewhere on the web.

Get Started

Before getting started with <u>The Basics</u>, we recommend reading one of the following introductory pages. These introductions are intended to highlight key similarities and differences between TypeScript and your favored programming language, and clear up common misconceptions specific to those languages.

- <u>TypeScript for New Programmers</u>
- <u>TypeScript for JavaScript Programmers</u>
- <u>TypeScript for OOP Programmers</u>
- <u>TypeScript for Functional Programmers</u>

Otherwise, jump to <u>The Basics</u> or grab a copy in <u>Epub</u> or <u>PDF</u> form.

The Basics

Each and every value in JavaScript has a set of behaviors you can observe from running different operations. That sounds abstract, but as a quick example, consider some operations we might run on a variable named message.

class="shiki light-plus" style="background-color: #FFFFFF; color: #000000"><div
class="language-id">js</div><div class='code-container'><code><div class='line'>// Accessing the property 'toLowerCase'</div><div class='line'>
// on 'message' and then calling it</div><div class='line'>
message.toLowerCase();</div>
<div class='line'></div><div class='line'>message<span
style="color: #

If we break this down, the first runnable line of code accesses a property called toLowerCase and then calls it. The second one tries to call message directly.

But assuming we don't know the value of message - and that's pretty common - we can't reliably say what results we'll get from trying to run any of this code. The behavior of each operation depends entirely on what value we had in the first place.

- Is message callable?
- Does it have a property called toLowerCase on it?
- If it does, is toLowerCase even callable?
- If both of these values are callable, what do they return?

The answers to these questions are usually things we keep in our heads when we write JavaScript, and we have to hope we got all the details right.

Let's say message was defined in the following way.

< div
class="language-id"> js < /div > < div class='code-container'> < code> < div class='line'> < span
style="color: #00000FF"> const < / span> < span style="color: #000000"> < / span> < span style="color: #0070C1"> message < / span> < span style="color: #000000"> = < / span> < span style="color: #000000"> ; < / span> < / div > < / code> < / div >

As you can probably guess, if we try to run <code>message.toLowerCase()</code>, we'll get the same string only in lower-case.

What about that second line of code? If you're familiar with JavaScript, you'll know this fails with an exception:

< div
class="language-id">txt</div> < div class='code-container'> < code> < div class='line'> < span
style="color: undefined"> TypeError: message is not a function < / span> < / div> < / code> < / div>

It'd be great if we could avoid mistakes like this.

When we run our code, the way that our JavaScript runtime chooses what to do is by figuring out the *type* of the value - what sorts of behaviors and capabilities it has. That's part of what that TypeError is alluding to - it's saying that the string "Hello World!" cannot be called as a function.

For some values, such as the primitives string and number, we can identify their type at runtime using the typeof operator. But for other things like functions, there's no corresponding runtime mechanism to identify their types. For example, consider this function:

<div
class="language-id">js</div> <div class='code-container'> <code> <div class='line'> function (x) { </div> <div class='line'> return x (x (); </div> <div class='line'> (); </div> </div>

We can *observe* by reading the code that this function will only work if given an object with a callable flip property, but JavaScript doesn't surface this information in a way that we can check while the code is running. The only way in pure JavaScript to tell what fn does with a particular value is to call it and see what happens. This kind of behavior makes it hard to predict what code will do before it runs, which means it's harder to know what your code is going to do while you're writing it.

Seen in this way, a *type* is the concept of describing which values can be passed to fn and which will crash. JavaScript only truly provides *dynamic* typing - running the code to see what happens.

The alternative is to use a *static* type system to make predictions about what code is expected *before* it runs.

Static type-checking

Think back to that TypeError we got earlier from trying to call a string as a function. *Most people* don't like to get any sorts of errors when running their code - those are considered bugs! And when we write new code, we try our best to avoid introducing new bugs.

If we add just a bit of code, save our file, re-run the code, and immediately see the error, we might be able to isolate the problem quickly; but that's not always the case. We might not have tested the feature thoroughly enough, so we might never actually run into a potential error that would be thrown! Or if we were lucky enough to witness the error, we might have ended up doing large refactorings and adding a lot of different code that we're forced to dig through.

Ideally, we could have a tool that helps us find these bugs *before* our code runs. That's what a static type-checker like TypeScript does. *Static types systems* describe the shapes and behaviors of what our values will be when we run our programs. A type-checker like TypeScript uses that information and tells us when things might be going off the rails.

<div class='code-container'> <code> <div class='line'> const <data-lsp lsp='const message: &quot;hello!&quot;'> message </data-lsp> = "hello!" ; </div> <div class='line'> <data-err> <data-lsp lsp='const message: &quot;hello!&quot;'> message </data-lsp> </data-err> < (); </div> This expression is not callable. Type 'String' has no call signatures. 2349 < </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBOAUAMZwB2iALqA </div>

Running that last sample with TypeScript will give us an error message before we run the code in the first place.

Non-exception Failures

So far we've been discussing certain things like runtime errors - cases where the JavaScript runtime tells us that it thinks something is nonsensical. Those cases come up because the ECMAScript specification has explicit instructions on how the language should behave when it runs into something unexpected.

For example, the specification says that trying to call something that isn't callable should throw an error. Maybe that sounds like "obvious behavior", but you could imagine that accessing a property

that doesn't exist on an object should throw an error too. Instead, JavaScript gives us different behavior and returns the value undefined:

<div
class="language-id">js</div> <div class='code-container'> <code> <div class='line'> const <span style="color:
#0070C1"> user = { </div> <div class='line'>
 name: "Daniel" </div> <div class='line'> ; </div> <div class='line'> style="color: #000000"> ; ; <span style="

Ultimately, a static type system has to make the call over what code should be flagged as an error in its system, even if it's "valid" JavaScript that won't immediately throw an error. In TypeScript, the following code produces an error about location not being defined:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const < data-lsp lsp='const user:</pre> {
 name: string;
 age: number;
}' >user</data-lsp> = {</div><div class='line'> <data-lsp lsp='(property) name: string' >name</datalsp>: "Daniel" ,</div><div class='line'> <data-lsp lsp='(property) age: number' >age</data-lsp>: 26,</div><div class='line'>};</div> <div class='line'><datalsp lsp='const user: {
 name: string;
 age: number;
}' >user</datalsp>.<data-err> <data-lsp lsp='any' >location</data-lsp></data-err>; </div>Property 'location' does not exist on type '{ name: string; age: number; \\.2339Property 'location' does not exist on type '{ name: string; age: number; }'.</code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQBjOAO0QBdQB.

</div>

While sometimes that implies a trade-off in what you can express, the intent is to catch legitimate bugs in our programs. And TypeScript catches *a lot* of legitimate bugs.

For example: typos,

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const <data-lsp lsp='const</pre> announcement: & amp;quot; Hello World! & amp;quot; '> announcement < /data-lsp> < /span> < span style="color: #000000"> = "Hello World!";</div> <div class='line'>// How quickly can you spot the typos?</div><div class='line'> <data-lsp lsp='const announcement: &quot;Hello World!&quot;' >announcement</datalsp>.<data-lsp lsp='any' >toLocaleLowercase</data-lsp>(); </div><div class='line'><data-lsp lsp='const announcement: "Hello World!"' >announcement</data-lsp>.<data-lsp lsp='any' >toLocalLowerCase</data-lsp>();</div> <div class='line'>// We probably meant to write this...</div> <div class='line'> <data-lsp lsp='const announcement:</pre> "Hello World!"' >announcement</data-lsp>.<data-lsp lsp='(method) String.toLocaleLowerCase(locales?: string | string[] | undefined): string' > toLocaleLowerCase</datalsp>();</div></code>Try</div>

uncalled functions,

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function flipCoin(): boolean' >flipCoin</data-lsp> () { </div> <div class='line'> // Meant to be Math.random() </div> <div class='line'> <data-lsp lsp='var Math: Math' >Math</data-lsp> . <span style="color

class='line'> < span style="color: #000000">} < / span > < / div > < / code > < a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEDsHsFVIK4GcCmATAMtAxgQwDZIBQIEKATudO < / div >

or basic logic errors.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const <data-lsp lsp='const</pre> value: "a" | "b"' >value</data-lsp> = <data-lsp lsp='var Math: Math' #795E26"> < data-lsp lsp='(method) Math.random(): number' > random < /data-lsp > < span style="color: #000000">() < 0.5? "a": "b" < span style="color: #000000">; </div><div class='line'>if (<data-lsp lsp='const value: "a" | "b"' >value</data-lsp> !== "a" < span style="color: #000000">) {</div><div class='line'> // ...</div><div class='line'>} else if (< data-lsp lsp='const value: & amp;quot;a& amp;quot;' > value < /data-lsp> === "b") {</div>This condition will always return 'false' since the types '"a"' and '"b"' have no overlap.2367This condition will always return 'false' since the types '"a"' and '"b"' have no overlap.<div class='line'> // Oops, unreachable</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYBsB2AUAMZwB2iALgA </div>

Types for Tooling

TypeScript can catch bugs when we make mistakes in our code. That's great, but TypeScript can also prevent us from making those mistakes in the first place.

The type-checker has information to check things like whether we're accessing the right properties on variables and other properties. Once it has that information, it can also start *suggesting* which properties you might want to use.

That means TypeScript can be leveraged for editing code too, and the core type-checker can provide error messages and code completion as you type in the editor. That's part of what people often refer to when they talk about tooling in TypeScript.

```
<!-- prettier-ignore --> class="shiki light-plus twoslash lsp" style="background-color:

```

href='https://www.typescriptlang.org/play/#code/PTAEAEDsHsFECd7XgZwFAggUxQWWgCYCuANlgJKQ. </div>

TypeScript takes tooling seriously, and that goes beyond completions and errors as you type. An editor that supports TypeScript can deliver "quick fixes" to automatically fix errors, refactorings to easily re-organize code, and useful navigation features for jumping to definitions of a variable, or finding all references to a given variable. All of this is built on top of the type-checker and is fully cross-platform, so it's likely that <u>your favorite editor has TypeScript support available</u>.

tsc , the TypeScript compiler

We've been talking about type-checking, but we haven't yet used our type-checker. Let's get acquainted with our new friend tsc, the TypeScript compiler. First we'll need to grab it via npm.

< div
class="language-id"> sh < / div > < div class='code-container' > < code > < div class='line' > < span
style="color: #000000" > npm install -g typescript < / span > < / div > < / code > < / div >

This installs the TypeScript Compiler tsc globally. You can use npx or similar tools if you'd prefer to run tsc from a local node_modules package instead.

Now let's move to an empty folder and try writing our first TypeScript program: hello.ts:

< div
class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Greets the
world. < /div> < div class='line'> < span style="color: #001080"> < data-lsp lsp='var console:
Console' > console</data-lsp> < /span> < span style="color: #000000"> . < /span> < span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
 < span style="color: #000000"> (< /span> < span style="color: #A31515"> "Hello world!"
 < span style="color: #000000">); < /span> < /div> < /code> < a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEHECcFNoFwM6jgC2qA7ge0gGwCYB0AUAMZYB2
</div>

Notice there are no frills here; this "hello world" program looks identical to what you'd write for a "hello world" program in JavaScript. And now let's type-check it by running the command tsc which was installed for us by the typescript package.

< div
class="language-id"> sh < / div > < div class='code-container'> < code> < div class='line'> < span
style="color: #000000"> tsc hello.ts < / span > < / div > < / code> < / div >

Tada!

Wait, "tada" *what* exactly? We ran tsc and nothing happened! Well, there were no type errors, so we didn't get any output in our console since there was nothing to report.

But check again - we got some *file* output instead. If we look in our current directory, we'll see a hello.js file next to hello.ts. That's the output from our hello.ts file after tsc *compiles* or *transforms* it into a plain JavaScript file. And if we check the contents, we'll see what TypeScript spits out after it processes a .ts file:

< div
class="language-id">js </div> < div class='code-container'> < code> < div class='line'> < span
style="color: #008000"> // Greets the world. < /div> < div class='line'> < span style="color:
#001080"> console < span style="color: #000000"> . < span style="color:
#795E26"> log < span style="color: #000000"> (< span style="color:
#A31515"> "Hello world!" < span style="color: #000000">); < /div> </code> < /div>

In this case, there was very little for TypeScript to transform, so it looks identical to what we wrote. The compiler tries to emit clean readable code that looks like something a person would write. While that's not always so easy, TypeScript indents consistently, is mindful of when our code spans across different lines of code, and tries to keep comments around.

What about if we *did* introduce a type-checking error? Let's rewrite hello.ts:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #008000"> // This is an industrial-grade general-purpose greeter function:</div><div class='line'>function < data-lsp lsp='function greet(person: any, date: any): void' > greet < /datalsp>(<data-lsp lsp='(parameter) person: any' >person</data-lsp>, <data-lsp lsp='(parameter) date: any' >date</data-lsp>) {</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span> (`Hello <span</pre> style="color: #0000FF">\${<data-lsp lsp='(parameter) person: any' >person</data-lsp>}, today is \${ < data-lsp lsp='(parameter) date: any' > date < /data-lsp > < span style="color: #0000FF">}!`);</div><div class='line'>}</div> <div class='line'> <data-lsp lsp='function greet(person: any, date:</pre> any): void' > greet < /data-lsp > < span style="color: #000000" > ("Brendan"); </div> </code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/PTAEAEDsHsFECd7XgZwFAIAFQBYEsVQDQBDSIyAEwFvHl0AFKOEodAGlCUSigJSgA3mlCh1O28x4AOmZodgsAAwAJHmYQ0AASd2tUHQBfBzpoJwBPlkJEp0VU@</div>

If we run tsc hello.ts again, notice that we get an error on the command line!

< div
class="language-id"> txt < / div > < div class='code-container' > < code > < div class='line' > < span
style="color: undefined" > Expected 2 arguments, but got 1. < / div > < / code > < / div >

TypeScript is telling us we forgot to pass an argument to the greet function, and rightfully so. So far we've only written standard JavaScript, and yet type-checking was still able to find problems with our code. Thanks TypeScript!

Emitting with Errors

One thing you might not have noticed from the last example was that our hello.js file changed again. If we open that file up then we'll see that the contents still basically look the same as our input file. That might be a bit surprising given the fact that tsc reported an error about our code, but this is based on one of TypeScript's core values: much of the time, you will know better than TypeScript.

To reiterate from earlier, type-checking code limits the sorts of programs you can run, and so there's a tradeoff on what sorts of things a type-checker finds acceptable. Most of the time that's okay, but there are scenarios where those checks get in the way. For example, imagine yourself migrating JavaScript code over to TypeScript and introducing type-checking errors. Eventually you'll get around to cleaning things up for the type-checker, but that original JavaScript code was already working! Why should converting it over to TypeScript stop you from running it?

So TypeScript doesn't get in your way. Of course, over time, you may want to be a bit more defensive against mistakes, and make TypeScript act a bit more strictly. In that case, you can use the --noEmitOnError compiler option. Try changing your hello.ts file and running tsc with that flag:

< div
class="language-id"> sh < / div > < div class='code-container' > < code > < div class='line' > < span
style="color: #000000" > tsc --noEmitOnError hello.ts < / / span > < / div > < / / code > < / div > < / / pre>

You'll notice that hello.js never gets updated.

Explicit Types

Up until now, we haven't told TypeScript what person or date are. Let's edit the code to tell TypeScript that person is a string, and that date should be a Date object. We'll also use the toDateString() method on date.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
greet(person: string, date: Date): void' > greet < /data-lsp > </span > < span style="color: #000000" >
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) person: string'
>person</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">, </span><span style="color: #001080">

</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAcwE4FN1QBQAd2oDOCAXIoVk
</div>
```

What we did was add *type annotations* on person and date to describe what types of values greet can be called with. You can read that signature as "greet takes a person of type string, and a date of type Date".

With this, TypeScript can tell us about other cases where we might have been called incorrectly. For example...

```
<data-lsp lsp='(parameter) date: Date' >date</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99"><data-lsp lsp='interface Date' > Date</data-lsp></span>
<span style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #A31515"> `Hello </span><span style="color:
#0000FF">${</span><span style="color: #001080"><data-lsp lsp='(parameter) person: string'
>person</data-lsp></span><span style="color: #0000FF">}</span><span style="color:
#A31515">, today is </span><span style="color: #0000FF">${</span><span style="color:
#001080"> < data-lsp lsp='(parameter) date: Date' > date</data-lsp> </span> < span style="color:
#000000FF">.</span><span style="color: #795E26"><data-lsp lsp='(method) Date.toDateString():
string' >toDateString</data-lsp></span><span style="color: #000000FF">()</span><span
style="color: #0000FF">}</span><span style="color: #A31515">!`</span><span style="color:
#000000">);</span></div><div class='line'><span style="color: #000000">}</span></div>
<div class='line'><span style="color: #795E26"> <data-lsp lsp='function greet(person: string, date:</pre>
Date): void' >greet</data-lsp></span><span style="color: #000000">(</span><span
style="color: #A31515">"Maddison"</span><span style="color: #000000">, </span><span
style="color: #267F99"> < data-lsp lsp='var Date: DateConstructor&amp;#13;() => string'
>Date</data-lsp></span><span style="color: #000000">());</span></div><span class="error">
<span>Argument of type 'string' is not assignable to parameter of type 'Date'.</span><span
class="code">2345</span></span><span class="error-behind">Argument of type 'string' is not
assignable to parameter of type 'Date'.</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAGYCuAdgMY/
</div>
```

Huh? TypeScript reported an error on our second argument, but why?

Perhaps surprisingly, calling Date() in JavaScript returns a string. On the other hand, constructing a Date with new Date() actually gives us what we were expecting.

Anyway, we can quickly fix up the error:

console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (`Hello \${<data-lsp</pre> lsp='(parameter) person: string' > person < /data-lsp> < /span> < span style="color: #0000FF">} , today is \${<data-lsp lsp='(parameter) date: Date' >date</data-lsp>. < data-lsp lsp='(method) Date.toDateString(): string' > toDateString < /data-lsp > ()}<span</pre> style="color: #A31515">!`);</div><div class='line dim'>}</div> <div class='line highlight'> < data-lsp lsp='function greet(person: string, date: Date): void' >greet</data-lsp>("Maddison", new <data-lsp lsp='var Date: DateConstructor&#13;new () => Date (+4 overloads)' > Date/datalsp>());</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAcwE4FN1QBQAd2oDOCAXIoVk </div>

Keep in mind, we don't always have to write explicit type annotations. In many cases, TypeScript can even just *infer* (or "figure out") the types for us even if we omit them.

Even though we didn't tell TypeScript that msg had the type string it was able to figure that out. That's a feature, and it's best not to add annotations when the type system would end up inferring the same type anyway.

Note: the message bubble inside the code sample above. That is what your editor would show if you had hovered over the word.

Erased Types

Let's take a look at what happens when we compile the above function greet with tsc to output JavaScript:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #A31515"> "use strict"
</span><span style="color: #000000">;</span></div><div class='line'><span style="color:
#795E26">greet</span><span style="color: #000000">(</span><span style="color:
#001080">person</span><span style="color: #000000">, </span><span style="color:
\#001080">date</span><span style="color: \#000000">) {</span></div><div class='line'><span
style="color: #000000"> </span> <span style="color: #001080"> console </span> <span
style="color: #000000">.</span><span style="color: #795E26">log</span><span style="color:
#000000">(</span><span style="color: #A31515">"Hello "</span><span style="color:
#000000"> + </span><span style="color: #001080">person</span><span style="color:
#000000"> + </span><span style="color: #A31515">", today is "</span><span style="color:
#000000"> + </span><span style="color: #001080">date</span><span style="color:
#000000">.</span><span style="color: #795E26">toDateString</span><span style="color:
#000000">() + </span><span style="color: #A31515">"!"</span><span style="color:
\#000000");</span></div><div class='line'><span style="color: \#000000">}</span></div><div
class='line'><span style="color: #795E26">greet</span><span style="color: #000000">(</span>
<span style="color: #A31515"> "Maddison" </span> < span style="color: #000000">, </span>
<span style="color: #0000FF">new</span><span style="color: #000000"> </span><span</pre>
style="color: #267F99"> Date</span> < span style="color: #000000">()); </span> </div> </code>
<a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEGcAsHsHcCiBbAlgFwFAgughgE4DmApugFygm
```

href='https://www.typescriptlang.org/play/#code/PTAEAEGcAsHsHcCiBbAlgFwFAgughgE4DmApugFygm AEIHHQBuTD9MTF5+dAEAIgBZPCUICK4yxWYSeFAEkgEdXKA'>Try </div>

Notice two things here:

- 1. Our person and date parameters no longer have type annotations.
- 2. Our "template string" that string that used backticks (the character) was converted to plain strings with concatenations (+).

More on that second point later, but let's now focus on that first point. Type annotations aren't part of JavaScript (or ECMAScript to be pedantic), so there really aren't any browsers or other runtimes that can just run TypeScript unmodified. That's why TypeScript needs a compiler in the first place - it needs some way to strip out or transform any TypeScript-specific code so that you can run it. Most TypeScript-specific code gets erased away, and likewise, here our type annotations were completely erased.

Remember: Type annotations never change the runtime behavior of your program.

Downleveling

One other difference from the above was that our template string was rewritten from

```
class="shiki light-plus" style="background-color: #FFFFFF; color: #000000"> <div
class="language-id">js </div > <div class='code-container' > <code> <div class='line' > <span
style="color: #A31515"> `Hello </span> <span style="color: #0000FF"> $ { </span> < span
style="color: #001080"> person </span> < span style="color: #0000FF"> } </span> < span
style="color: #A31515">, today is </span> < span style="color: #00000FF"> $ { </span> < span
style="color: #001080"> date </span> < span style="color: #000000FF"> . </span> < span
style="color: #795E26"> toDateString </span> < span style="color: #000000FF"> () </span> < span
style="color: #00000FF"> } </span> < span style="color: #A31515"> !` </span> < span style="color: #000000"> ; </span> < span style="color: #000000"> ; </span> < span style="color: #000000"> ; </span> < span style="color: #00000"> ; </span> < </span> < span style="color: #00000"> ; </span> < span style="c
```

to

< div
class="language-id">js</div> < div class='code-container'> < code> < div class='line'> < span
style="color: #A31515"> "Hello " < span style="color: #000000"> + < span
style="color: #001080"> person < span style="color: #000000"> + < span
style="color: #A31515"> ", today is " < span style="color: #000000"> + < span
style="color: #001080"> date < span style="color: #000000"> . < span style="color: #795E26"> toDateString < span style="color: #000000"> () + < span style="color: #A31515"> "!" < span style="color: #000000"> ; < /div> </code> < /div>

Why did this happen?

Template strings are a feature from a version of ECMAScript called ECMAScript 2015 (a.k.a. ECMAScript 6, ES2015, ES6, etc. - *don't ask*). TypeScript has the ability to rewrite code from newer versions of ECMAScript to older ones such as ECMAScript 3 or ECMAScript 5 (a.k.a. ES3 and ES5). This process of moving from a newer or "higher" version of ECMAScript down to an older or "lower" one is sometimes called *downleveling*.

By default TypeScript targets ES3, an extremely old version of ECMAScript. We could have chosen something a little bit more recent by using the --target flag. Running with --target es2015 changes TypeScript to target ECMAScript 2015, meaning code should be able to run wherever ECMAScript 2015 is supported. So running tsc --target es2015 hello.ts gives us the following output:

< div
class="language-id">js </div > < div class='code-container'> < code> < div class='line'> < span
style="color: #00000FF"> function < / span> < span style="color: #000000"> < / span> < span
style="color: #795E26"> greet < / span> < span style="color: #000000"> (< / span> < span style="color: #001080"> person < / span> < span style="color: #000000">, < / span> < span style="color: #00000">, < / span> < span style="color: #000000">, < / span > style="color: #000000

```
#001080">date</span><span style="color: #000000">) {</span></div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">console</span><span style="color: #000000">.</span><span style="color: #795E26">log</span><span style="color: #000000">.</span><span style="color: #795E26">log</span><span style="color: #000000">.</span><span style="color: #31515"> Hello </span><span style="color: #00000FF">${</span><span style="color: #001080">person</span><span style="color: #0000FF">}</span><span style="color: #001080">date</span><span style="color: #0000FF">${</span><span style="color: #001080">date</span><span style="color: #00000FF">.</span><span style="color: #001080">date</span><span style="color: #00000FF">.</span><span style="color: #00000FF">}</span><span style="color: #00000FF">}</span><span style="color: #00000FF">>}</span><span style="color: #00000FF">>}</span><span style="color: #000000">);</span></div><div class='line'><span style="color: #000000">,</span><span style="color: #000000">,</span></span></span></span></span></span>
```

While the default target is ES3, the great majority of current browsers support ES2015. Most developers can therefore safely specify ES2015 or above as a target, unless compatibility with certain ancient browsers is important.

Strictness

Different users come to TypeScript looking for different things in a type-checker. Some people are looking for a more loose opt-in experience which can help validate only some parts of their program, and still have decent tooling. This is the default experience with TypeScript, where types are optional, inference takes the most lenient types, and there's no checking for potentially null / undefined values. Much like how tsc emits in the face of errors, these defaults are put in place to stay out of your way. If you're migrating existing JavaScript, that might be a desirable first step.

In contrast, a lot of users prefer to have TypeScript validate as much as it can straight away, and that's why the language provides strictness settings as well. These strictness settings turn static type-checking from a switch (either your code is checked or not) into something closer to a dial. The further you turn this dial up, the more TypeScript will check for you. This can require a little extra work, but generally speaking it pays for itself in the long run, and enables more thorough checks and more accurate tooling. When possible, a new codebase should always turn these strictness checks on.

TypeScript has several type-checking strictness flags that can be turned on or off, and all of our examples will be written with all of them enabled unless otherwise stated. The --strict flag in the CLI, or "strict": true in a tsconfig. json toggles them all on simultaneously, but we

can opt out of them individually. The two biggest ones you should know about are noImplicitAny and strictNullChecks.

noImplicitAny

Recall that in some places, TypeScript doesn't try to infer any types for us and instead falls back to the most lenient type: any . This isn't the worst thing that can happen - after all, falling back to any is just the plain JavaScript experience anyway.

However, using any often defeats the purpose of using TypeScript in the first place. The more typed your program is, the more validation and tooling you'll get, meaning you'll run into fewer bugs as you code. Turning on the noImplicitAny flag will issue an error on any variables whose type is implicitly inferred as any.

strictNullChecks

By default, values like null and undefined are assignable to any other type. This can make writing some code easier, but forgetting to handle null and undefined is the cause of countless bugs in the world - some consider it a <u>billion dollar mistake!</u> The <u>strictNullChecks</u> flag makes handling null and undefined more explicit, and *spares* us from worrying about whether we *forgot* to handle null and undefined.

Everyday Types

In this chapter, we'll cover some of the most common types of values you'll find in JavaScript code, and explain the corresponding ways to describe those types in TypeScript. This isn't an exhaustive list, and future chapters will describe more ways to name and use other types.

Types can also appear in many more *places* than just type annotations. As we learn about the types themselves, we'll also learn about the places where we can refer to these types to form new constructs.

We'll start by reviewing the most basic and common types you might encounter when writing JavaScript or TypeScript code. These will later form the core building blocks of more complex types.

The primitives: string, number, and boolean

JavaScript has three very commonly used <u>primitives</u>: string, number, and boolean. Each has a corresponding type in TypeScript. As you might expect, these are the same names you'd see if you used the JavaScript typeof operator on a value of those types:

- string represents string values like "Hello, world"
- number is for numbers like 42. JavaScript does not have a special runtime value for integers, so there's no equivalent to int or float everything is simply number
- boolean is for the two values true and false

The type names String, Number, and Boolean (starting with capital letters) are legal, but refer to some special built-in types that will very rarely appear in your code. *Always* use String, number, or boolean for types.

Arrays

To specify the type of an array like [1, 2, 3], you can use the syntax number[]; this syntax works for any type (e.g. string[] is an array of strings, and so on). You may also see this written as Array<number>, which means the same thing. We'll learn more about the syntax T<U> when we cover *generics*.

Note that [number] is a different thing; refer to the section on tuple types.

any

TypeScript also has a special type, any, that you can use whenever you don't want a particular value to cause typechecking errors.

When a value is of type any, you can access any properties of it (which will in turn be of type any), call it like a function, assign it to (or from) a value of any type, or pretty much anything else that's syntactically legal:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span > < span style="color: #000000"> <data-lsp lsp='let obj: any' >obj</data-lsp>: any = { <data-lsp lsp='(property) x: number' >x</data-lsp>: 0 }; </div> < div class='line' > < span style="color: #008000" > // None of the following lines of code will throw compiler errors.</div><div class='line'>// Using 'any' disables all further type checking, and it is assumed </div><div class='line'> // you know the environment better than TypeScript. </div><div class='line'><data-lsp lsp='let obj: any' >obj</datalsp>.<data-lsp lsp='any' >foo</data-lsp>();</div><div class='line'> < span style="color: #795E26"> < data-lsp lsp='let obj: any' > obj < /data-lsp> < /span> ();</div><div class='line'> <data-lsp lsp='let obj: any' >obj</data-lsp>. <data-lsp lsp='any' > bar </data-lsp> <span style="color:</pre> #000000" = 100;</div><div class='line'><data-lsp lsp='let obj: any' >obj </data-lsp> = "hello";</div><div class='line'>const < data-lsp lsp='const n: number' > n < / data-lsp > < / span > < span style="color: #000000">: number number number number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999 = < data-lsp lsp='let obj: any' > obj </data-lsp> ;</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/DYUwLgBA9gRgVgLggQwHYE8IF4IG8IAeSADBAL4Dc/ </div>

The any type is useful when you don't want to write out a long type just to convince TypeScript that a particular line of code is okay.

When you don't specify a type, and TypeScript can't infer it from context, the compiler will typically default to any.

You usually want to avoid this, though, because any isn't type-checked. Use the compiler flag noImplicitAny to flag any implicit any as an error.

Type Annotations on Variables

When you declare a variable using <code>const</code>, <code>var</code>, or <code>let</code>, you can optionally add a type annotation to explicitly specify the type of the variable:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span> < span style="color: #000000"> < / span> < span style="color: #001080"> < data-lsp lsp='let myName: string' > myName < / data-lsp> < / span> < span style="color: #000000"> : < / span> < span style="color: #000000"> : < / span> < span style="color: #000000"> = < / span> < span style="color: #000000"> ; < / span> < / div> < / code> < a class='playground-link'</pre>
```

href='https://www.typescriptlang.org/play/#code/DYUwLgBAtgngcgQyiAXBAzmATgSwHYDmEAvBAEQC </div>

TypeScript doesn't use "types on the left"-style declarations like int x = 0; Type annotations will always go *after* the thing being typed.

In most cases, though, this isn't needed. Wherever possible, TypeScript tries to automatically *infer* the types in your code. For example, the type of a variable is inferred based on the type of its initializer:

< div
class='code-container'> < code> < div class='line'> < span style="color: #008000"> // No type
annotation needed -- & apos;myName' inferred as type & apos;string' < /div>
<div class='line'> < span style="color: #00000FF"> let < / span> < span style="color: #000000"> <
/span> < span style="color: #001080"> < data-lsp lsp='let myName: string' > myName < / data-lsp>
 < span style="color: #000000"> = < span style="color: #A31515"> "Alice" < / span>
; < / span> < / div> < / code> < a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEDkHtQFwTwA4FNQEMB27I1TAlpOqOkkgCbmgCl
</div>

For the most part you don't need to explicitly learn the rules of inference. If you're starting out, try using fewer type annotations than you think - you might be surprised how few you need for TypeScript to fully understand what's going on.

Functions

Functions are the primary means of passing data around in JavaScript. TypeScript allows you to specify the types of both the input and output values of functions.

Parameter Type Annotations

When you declare a function, you can add type annotations after each parameter to declare what types of parameters the function accepts. Parameter type annotations go after the parameter name:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000">// Parameter type
annotation</span></div><div class='line'><span style="color: #0000FF">function</span><span
style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function
greet(name: string): void' > greet < /data-lsp > </span > <span style="color: #000000" > (</span >
<span style="color: #001080"> <data-lsp lsp='(parameter) name: string' > name < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">string</span>
<span style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #A31515">"Hello, "</span><span style="color:
#000000"> + </span><span style="color: #001080"> < data-lsp lsp='(parameter) name: string'
>name</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) String.toUpperCase(): string' > toUpperCase < /data-lsp>
</span><span style="color: #000000">() + </span><span style="color: #A31515">"!!"</span>
<span style="color: #000000">);</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAUEMCdIWwKYBcHVEgngBwaSA7fAeyUiQEsj8Ac
</div>
```

When a parameter has a type annotation, arguments to that function will be checked:

< div class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Would be a runtime error if executed! < / span> < / div> < div class='line'> < span style="color: #795E26"> < data-lsp lsp='function greet(name: string): void' > greet < / data-lsp> < / span> < span style="color: #000000"> (< / span> < span style="color: #098658"> < data-err> < 42 < / data-err> < / span> < span style="color: #000000">); < / span> < / div> < span class="error"> < span> Argument of type 'number' is not assignable to parameter of type 'string'. < / span> < span class="error-behind"> Argument of type 'number' is not assignable to parameter of type 'string'. < / span> < / code> < a class='playground-link'</pre>

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUACaQDGANglk </div>

Even if you don't have type annotations on your parameters, TypeScript will still check that you passed the right number of arguments.

Return Type Annotations

You can also add return type annotations. Return type annotations appear after the parameter list:

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function getFavoriteNumber(): number' > getFavoriteNumber </data-lsp> (): number </div> <div class='line'> </div> </di>

Much like variable type annotations, you usually don't need a return type annotation because TypeScript will infer the function's return type based on its return statements. The type annotation in the above example doesn't change anything. Some codebases will explicitly specify a return type for documentation purposes, to prevent accidental changes, or just for personal preference.

Anonymous Functions

Anonymous functions are a little bit different from function declarations. When a function appears in a place where TypeScript can determine how it's going to be called, the parameters of that function are automatically given types.

Here's an example:

< div
class='code-container'> < code> < div class='line'> < span style="color: #008000"> // No type
annotations here, but TypeScript can spot the bug < / div> < div class='line'> < span
style="color: #0000FF"> const < span style="color: #000000"> < / span> < span style="color: #0070C1"> < data-lsp lsp='const names: string[]' > names < / data-lsp> < span style="color: #000000"> = [< / span> < span style="color: #A31515"> "Alice" < / span> < span style="color: #000000"> , < / span> < span style="color: #A31515"> "Bob" < / span> < span style="color: #000000"> < span style="color: #000000"> < / span> < span style="color: #000000"> < span s

```
#000000">, </span><span style="color: #A31515">"Eve"</span><span style="color:

</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYMEYBQJQA5OUAFwE8/
</div>
```

Even though the parameter s didn't have a type annotation, TypeScript used the types of the forEach function, along with the inferred type of the array, to determine the type s will have.

This process is called *contextual typing* because the *context* that the function occurred in informed what type it should have. Similar to the inference rules, you don't need to explicitly learn how this happens, but understanding that it *does* happen can help you notice when type annotations aren't needed. Later, we'll see more examples of how the context that a value occurs in can affect its type.

Object Types

Apart from primitives, the most common sort of type you'll encounter is an *object type*. This refers to any JavaScript value with properties, which is almost all of them! To define an object type, we simply list its properties and their types.

For example, here's a function that takes a point-like object:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000">// The
parameter's type annotation is an object type</span></div><div class='line'><span
style="color: #0000FF">function</span><span style="color: #000000"> </span><span
style="color: #795E26"> < data-lsp lsp='function printCoord(pt: {&amp;#13; x: number;&amp;#13;
y: number;
}): void' >printCoord</data-lsp></span><span style="color: #000000">
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) pt: {&amp;#13; x:
number;
 y: number;
}' >pt</data-lsp></span><span style="color:
#000000">: { </span> < span style="color: #001080"> < data-lsp lsp='(property) x: number'
>x</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000">; </span><span style="color:
#001080"> < data-lsp lsp='(property) y: number' > y < /data-lsp > </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F999999
#000000"> }) {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span> < span
style="color: #000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Console.log(...data: any[]): void' >log</data-lsp></span><span style="color: #000000">(</span>
<span style="color: #A31515"> "The coordinate&apos;s x value is "</span> < span style="color:</pre>
#000000"> + </span><span style="color: #001080"> < data-lsp lsp='(parameter) pt: {&amp;#13; x:
number;
 y: number;
}' >pt</data-lsp></span><span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property) x: number'
>x</data-lsp></span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #000000"> </span> < span style="color: #001080"> < data-lsp lsp='var console:
Console' > console < /data-lsp > </span > < span style="color: #000000">.</span > < span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #A31515">"The
coordinate's y value is "</span><span style="color: #000000"> + </span><span
```

style="color: #001080" > <data-lsp lsp='(parameter) pt: {&#13; x: number;&#13; y: number;&#13;}' > pt</data-lsp > . .); </div > <div class='line' >); </div > <div class='line' > } </div > <div class='line' > <data-lsp lsp='function printCoord(pt: {&#13; x: number;&#13; y: number;&#13;}): void' > printCoord </data-lsp > ({ <data-lsp lsp='(property) x: number' > x</data-lsp>: <data-lsp lsp='(property) y: number' > y</data-lsp>: }); </div > </code > Try </div > </div

Here, we annotated the parameter with a type with two properties - x and y - which are both of type number . You can use , or ; to separate the properties, and the last separator is optional either way.

The type part of each property is also optional. If you don't specify a type, it will be assumed to be any .

Optional Properties

Object types can also specify that some or all of their properties are *optional*. To do this, add a ? after the property name:

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function printName(obj: {&#13; first: string;&#13; last?: string;&#13;}): void' > printName</data-lsp> (<data-lsp lsp='(parameter) obj: {&#13; first: string;&#13; last?: string | undefined;&#13;}' > obj </data-lsp > : { : { : string ; </div> <div class='line'> // ... </div> <div class='line'> </div> <div class='line'> </div> <div class='line'> </div> <div class='line'> </div> <div class='line'> // ... </div> <div class='line'> // ...

```
#795E26"> <data-lsp lsp='function printName(obj: {&amp;#13; first: string;&amp;#13; last?: string;&amp;#13;}): void' > printName </data-lsp > </span > <span style="color: #000000"> </span > <span style="color: #000000"> </span > <span style="color: #000000"> </span > <span style="color: #31515"> "Bob" </span > <span style="color: #000000"> </span > <span style="color: #31515"> "Bob" </span > <span style="color: #000000"> }); </span > </div > <div class='line' > <span style="color: #795E26"> <data-lsp lsp='function printName(obj: {&amp;#13; first: string;&amp;#13; last?: string;&amp;#13;}): void' > printName </data-lsp > </span > <span style="color: #000000"> </span > <span style="color: #000000"> </span > <span style="color: #000000"> </span > <span style="color: #31515"> "Alice" </span > <span style="color: #000000"> <span > <span style="color: #000000"> <span > <span style="color: #000000"> <span > <
```

In JavaScript, if you access a property that doesn't exist, you'll get the value undefined rather than a runtime error. Because of this, when you *read* from an optional property, you'll have to check for undefined before using it.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> printName(obj: {
 first: string;
 last?: string;
}): void' >printName</data-lsp>(< data-lsp lsp='(parameter) obj: {&#13; first: string;&#13; last?: string | undefined;
}' >obj</data-lsp>: { < data-lsp lsp='(property) first: string' > first < /data-lsp > < span style="color: #000000">: string; <data-lsp lsp='(property) last?: string | undefined' > last < /data-lsp > ?: string }) {</div><div class='line'> // Error might crash if 'obj.last' wasn't provided! </div> <div class='line'> <data-lsp lsp='var</pre> console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp lsp='(parameter) obj: {

 last?: string | undefined;
}' >obj</data-lsp>. <data-lsp lsp='(property) last?: string | undefined' > last</data-lsp>.<data-lsp lsp='(method) String.toUpperCase(): string' >toUpperCase</data-lsp>());</div><span

class="error"> < span > Object is possibly 'undefined'. < / span > < span class="code" > 2532 < / span > Object is possibly 'undefined'.<div class='line'> if<span</pre> style="color: #000000"> (<data-lsp lsp='(parameter) obj: {
 first: string;
 last?: string | undefined;
}' >obj </data-lsp> .<data-lsp lsp='(property)</pre> last?: string | undefined' > last < /data-lsp > < span style="color: #000000" > !== < data-lsp lsp='var undefined' > undefined < /data-lsp> < /span>) {</div><div class='line'> // OK</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span> (<data-lsp</pre> lsp='(parameter) obj: {
 first: string;
 last?: string | undefined;
}' >obj</data-lsp>. <data-lsp lsp='(property) last?: string' >last</data-lsp>. <data-lsp lsp='(method) String.toUpperCase(): string' >toUpperCase</data-lsp>());</div><div class='line'> }</div> <div class='line'> // A safe alternative using modern JavaScript syntax:</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp> .<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(<data-lsp lsp='(parameter) obj: {&#13; first: string;
 last?: string | undefined;
}' >obj </data-lsp> < span style="color: #000000">.<data-lsp lsp='(property) last?: string | undefined' >last</data-lsp>?. < data-lsp lsp='(method) String.toUpperCase(): string' >toUpperCase</data-lsp>());</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMaBQAzAVwDsBjAFw qDIYREeWQC8Q6AkGeLEmcam5uaWAPIA0rnmpPmFxSqlfZUyNfWNLW3cHV3m+ri5lgCColhs+JCgbCrl </div>

Union Types

TypeScript's type system allows you to build new types out of existing ones using a large variety of operators. Now that we know how to write a few types, it's time to start *combining* them in interesting ways.

Defining a Union Type

</div>

The first way to combine types you might see is a *union* type. A union type is type formed from two or more other types, representing values that may be *any one* of those types. We refer to each of these types as the union's *members*.

Let's write a function that can operate on strings or numbers:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
printld(id: number | string): void' > printld < /data-lsp > </span > < span style="color: #000000" >
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) id: string | number'
>id</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000"> | </span><span style="color:
#267F99">string</span><span style="color: #000000">) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='var</pre>
console: Console' >console</data-lsp></span><span style="color: #000000">.</span><span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #A31515">"Your ID is: "
</span><span style="color: #000000"> + </span><span style="color: #001080"> < data-lsp
lsp='(parameter) id: string | number' >id</data-lsp></span><span style="color: #000000">);
</span></div><div class='line'><span style="color: #000000">}</span></div><div
class='line'><span style="color: #008000">// OK</span></div><div class='line'><span
style="color: #795E26"> < data-lsp lsp='function printld(id: number | string): void' > printld < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #098658">101</span>
<span style="color: #000000">);</span></div><div class='line'><span style="color:</pre>
#008000">// OK</span></div><div class='line'><span style="color: #795E26"><data-lsp
lsp='function printld(id: number | string): void' > printld < /data-lsp > </span > < span style="color:
#000000">(</span><span style="color: #A31515">"202"</span><span style="color:
#000000">);</span></div><div class='line'><span style="color: #008000">// Error</span>
</div><div><div class='line'><span style="color: #795E26"><data-lsp lsp='function printld(id: number
| string): void' > printld < /data-lsp > </span > <span style="color: #000000" > ({ </span > <span
style="color: #001080"> < data-lsp lsp='(property) myID: number' > myID < /data-lsp >: </span>
<span style="color: #000000"> </span><span style="color: #098658">22342</span><span</pre>
style="color: #000000"> });</span></div><span class="error"><span>Argument of type '{ myID:
number; }' is not assignable to parameter of type 'string | number'. Type '{ myID: number; }' is not
assignable to type 'number'.</span><span class="code">2345</span></span><span
class="error-behind">Argument of type '{ myID: number; }' is not assignable to parameter of type
'string | number'. Type '{ myID: number; }' is not assignable to type 'number'. </span> </code> <a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAGYCuAdgMY/
```

Working with Union Types

It's easy to *provide* a value matching a union type - simply provide a type matching any of the union's members. If you *have* a value of a union type, how do you work with it?

TypeScript will only allow you to do things with the union if that thing is valid for *every* member of the union. For example, if you have the union string | number, you can't use methods that are only available on string:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> printld(id: number | string): void' > printld < /data-lsp > < span style="color: #000000" > (< span style="color: #001080"> < data-lsp lsp='(parameter) id: string | number' >id</data-lsp>: number | string) {</div><div class='line'> <data-lsp lsp='var</pre> console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp lsp='(parameter) id: string | number' >id</data-lsp> < span style="color: #000000">. <data-err><data-lsp lsp='any' >toUpperCase</data-lsp> </data-err>());</div> Property 'toUpperCase' does not exist on type 'string | number'. Property 'toUpperCase' does not exist on type 'number'.2339Property 'toUpperCase' does not exist on type 'string | number'. Property 'toUpperCase' does not exist on type 'number'.<div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQAzAVwDsBjAFw </div>

The solution is to *narrow* the union with code, the same as you would in JavaScript without type annotations. *Narrowing* occurs when TypeScript can deduce a more specific type for a value based on the structure of the code.

For example, TypeScript knows that only a string value will have a typeof value "string":

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </ span>
 < span style="color: #000000"> </ span> < span style="color: #795E26"> < data-lsp lsp='function
 printld(id: number | string): void' > printld < / data-lsp> < / span> < span style="color: #000000">
 (</ span> < span style="color: #001080"> < data-lsp lsp='(parameter) id: string | number'
 > id < / data-lsp> < / span> < span style="color: #000000">: < / span> < span style="color: #000000">

```
#267F99">number</span><span style="color: #000000"> | </span><span style="color:
#267F99">string</span><span style="color: #000000">) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #AF00DB">if</span><span</pre>
style="color: #000000"> (</span><span style="color: #0000FF">typeof</span><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) id:
string | number' >id</data-lsp></span><span style="color: #000000"> === </span><span
style="color: #A31515"> "string" </span> < span style="color: #000000">) {</span> </div> < div
class='line'><span style="color: #000000"> </span><span style="color: #008000">// In this
branch, id is of type 'string'</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='var console: Console'
>console</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span>
<span style="color: #000000">(</span><span style="color: #001080"><data-lsp</pre>
lsp='(parameter) id: string' >id</data-lsp></span><span style="color: #000000">.</span><span
style="color: #795E26"> < data-lsp lsp='(method) String.toUpperCase(): string'
>toUpperCase</data-lsp></span><span style="color: #000000">());</span></div><div
class='line'><span style="color: #000000"> } </span><span style="color:
#AF00DB">else</span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #008000">// Here, id is of type
'number'</span></div><div class='line'><span style="color: #000000"> </span>
<span style="color: #001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span>
<span style="color: #000000">.</span><span style="color: #795E26"> < data-lsp lsp='(method)</pre>
Console.log(...data: any[]): void' >log</data-lsp></span><span style="color: #000000">(</span>
<span style="color: #001080"> <data-lsp lsp='(parameter) id: number' >id</data-lsp> </span>
<span style="color: #000000">);</span></div><div class='line'><span style="color: #000000">
}</span> </div> < div class='line'> < span style="color: #000000">}</span> </div> </code> < a</pre>
class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABABwE4zFAkgEwBQw4BciYIAtgEYu
</div>
```

Another example is to use a function like Array.isArray:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </span> < span style="color: #000000"> </span> < span style="color: #795E26"> < data-lsp lsp='function welcomePeople(x: string[] | string): void' > welcomePeople < / data-lsp> < / span> < span style="color: #001080"> < data-lsp lsp='(parameter) x: string | string[]' > x < / data-lsp> < / span> < span style="color: #000000">: </span> < span style="color: #267F99"> string </span> < span style="color: #000000"> [] | </span> < span style="color: #267F99"> string </span> < span style="color: #000000">) { </span> < /div> < div class='line'> < span style="color: #000000"> </span> < span style="color: #267F99"> < data-lsp lsp='var Array: ArrayConstructor' > Array < / data-lsp> </span> < span style="color: #000000">.</span> < span style="color: #267F99"> < data-lsp lsp='var Array: ArrayConstructor' > Array < / data-lsp> </span> < span style="color: #000000">.</span> < sp
```

```
style="color: #795E26"> < data-lsp lsp='(method) ArrayConstructor.isArray(arg: any): arg is any[]'
>isArray</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) x: string | string[]' > x < /data-lsp > < /span > < span
style="color: #000000">)) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #008000">// Here: &apos;x&apos; is &apos;string[]&apos;</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='var console: Console' >console</data-lsp></span><span style="color: #000000">.
</span><span style="color: #795E26"><data-lsp lsp='(method) Console.log(...data: any[]): void'
>log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"Hello, "</span><span style="color: #000000"> + </span><span style="color:
#001080"> < data-lsp lsp='(parameter) x: string[]' >x < /data-lsp> < /span> < span style="color:

Array<string>.join(separator?: string | undefined): string' >join</data-lsp></span><span
style="color: #000000">(</span><span style="color: #A31515">" and "</span><span
style="color: #000000">));</span></div><div class='line'><span style="color: #000000">}
</span><span style="color: #AF00DB">else</span><span style="color: #000000"> {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #008000">//
Here: 'x' is 'string'</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='var console: Console'
>console</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span>
<span style="color: #000000">(</span><span style="color: #A31515">"Welcome lone traveler "
</span><span style="color: #000000"> + </span><span style="color: #001080"> < data-lsp
lsp='(parameter) x: string' >x</data-lsp></span><span style="color: #000000">);</span></div>
<div class='line'><span style="color: #000000"> }</span></div><div class='line'><span</pre>
style="color: #000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAdwKYBsJwLaoAqpwAO6qAFAB4
</div>
```

Notice that in the else branch, we don't need to do anything special - if x wasn't a string[], then it must have been a string.

Sometimes you'll have a union where all the members have something in common. For example, both arrays and strings have a slice method. If every member in a union has a property in common, you can use that property without narrowing:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Return type is inferred as number[] | string < / span> < / div > < div class='line'> < span style="color: #0000FF"> function < / /span> < span style="color: #000000"> < / /span> < span style="color: #795E26"> < data-lsp lsp='function getFirstThree(x: number[] | string): string | number[]' > getFirstThree < / /data-lsp < / /span> < span style="color: #000000"> (< / span> < span style="color: #001080"> < data-lsp lsp='(parameter) x: string | number[]' > x < / data-lsp < / span> < span style="color: #267F99"> number < / span> < span < span </pre>
```

style="color: #000000">[] | string (</div> <div class='line'> <data-lsp lsp='(parameter) x: string | number[]' >x</data-lsp> . <data-lsp lsp='(method) slice(start?: number | undefined, end?: number | undefined): string | number[]' >slice</data-lsp> ((0 , 3); </div> <div class='line'> (</div> <div class='line'> (</div> <div class='line'> (</div> <div class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAECUFMBcFcCcB2poE8AOIQEsDOPEAzSeeSAE1AEN IQEpQAb2GhQZOEIB6AdLgA22CboAGABpQAGZrAG5hAF8gA'>Try </div> </div>

It might be confusing that a *union* of types appears to have the *intersection* of those types' properties. This is not an accident - the name *union* comes from type theory. The *union* number | string is composed by taking the union of the values from each type. Notice that given two sets with corresponding facts about each set, only the *intersection* of those facts applies to the *union* of the sets themselves. For example, if we had a room of tall people wearing hats, and another room of Spanish speakers wearing hats, after combining those rooms, the only thing we know about *every* person is that they must be wearing a hat.

Type Aliases

We've been using object types and union types by writing them directly in type annotations. This is convenient, but it's common to want to use the same type more than once and refer to it by a single name.

A type alias is exactly that - a name for any type. The syntax for a type alias is:

<div class='code-container'> <code> <div class='line'> type < <data-lsp lsp='type Point = {&#13; x: number;&#13; y: number;&#13;}' > Point </data-lsp> = { </div> <div class='line'> <data-lsp lsp='(property) x: number' > x</data-lsp> : number <data-lsp lsp='(property) y: number' > y</data-lsp> : number number n

```
style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function
printCoord(pt: Point): void' > printCoord < /data-lsp > </span > < span style="color: #000000" >
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) pt: Point' > pt < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99"> < data-lsp
lsp='type Point = {
 x: number;
 y: number;
}' > Point < /data-lsp>
</span><span style="color: #000000">) {</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='var console: Console'
>console</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span>
<span style="color: #000000">(</span><span style="color: #A31515"> "The coordinate&apos;s x
value is "</span><span style="color: #000000"> + </span><span style="color: #001080"> < data-
lsp lsp='(parameter) pt: Point' >pt</data-lsp></span><span style="color: #000000">.</span>
<span style="color: #001080"> <data-lsp lsp='(property) x: number' > x < /data-lsp > </span > <span</pre>
style="color: #000000">);</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #A31515">"The coordinate&apos;s y value is "</span>
<span style="color: #000000"> + </span><span style="color: #001080"> < data-lsp</pre>
lsp='(parameter) pt: Point' >pt</data-lsp></span><span style="color: #000000">.</span><span
style="color: #001080"> < data-lsp lsp='(property) y: number' > y < /data-lsp > </span> < span
style="color: #000000">);</span></div><div class='line'><span style="color: #000000">}
</span></div> <div class='line'><span style="color: #795E26"><data-lsp lsp='function
printCoord(pt: Point): void' > printCoord < /data-lsp > </span > < span style="color: #000000" > ({
</span><span style="color: #001080"> <data-lsp lsp='(property) x: number' >x</data-lsp>:
</span> < span style="color: #000000"> </span> < span style="color: #098658"> 100 < /span>
<span style="color: #000000">, </span><span style="color: #001080"> < data-lsp lsp='(property)</pre>
y: number' >y</data-lsp>:</span><span style="color: #000000"> </span><span style="color:
#098658">100</span><span style="color: #000000"> });</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBACg9gSwHbCgXigbwFBSgDwC4okBXAW
CCGPHCkSJi4xNT09y9s3IKmErKKqCqoGvq-
aJAW7A5sbEdnN0zvTAJiAEYABj2AGiZdg6gOFgA'>Try</a></div>
```

You can actually use a type alias to give a name to any type at all, not just an object type. For example, a type alias can name a union type:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type </ span> < span style="color: #000000"> </ span> < span style="color: #267F99"> < data-lsp lsp='type ID = string | number' > ID < / data-lsp> < / span> < span style="color: #000000"> = </ span> < span style="color: #267F99"> number < / span> < span style="color: #000000"> | </ span> < span style="color: #267F99"> string < / span> < span style="color: #000000"> ; < / span> < / div> < / code> < a class='playground-link'</pre>
```

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAkgllAvFAdgVwLYCMlCcoA+UAzsLgJYoDr </div>

Note that aliases are *only* aliases - you cannot use type aliases to create different/distinct "versions" of the same type. When you use the alias, it's exactly as if you had written the aliased type. In other words, this code might *look* illegal, but is OK according to TypeScript because both types are aliases for the same type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
UserInputSanitizedString = string' > UserInputSanitizedString < /data-lsp > </span > <span
style="color: #000000"> = </span><span style="color: #267F99">string</span><span
style="color: #000000">;</span></div> <div class='line'> <span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function sanitizeInput(str: string): UserInputSanitizedString'
>sanitizeInput</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> <data-lsp lsp='(parameter) str: string' > str </data-lsp> </span> < span style="color:
#000000">): </span> < span style="color: #267F99"> < data-lsp lsp='type UserInputSanitizedString
= string' >UserInputSanitizedString</data-lsp></span><span style="color: #000000"> {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='function sanitize(str: string): string' >sanitize</data-lsp></span><span
style="color: #000000">(</span><span style="color: #001080"> < data-lsp lsp='(parameter) str:
string' >str</data-lsp></span><span style="color: #000000">);</span></div><div class='line'>
<span style="color: #000000">}</span></div> <div class='line'><span style="color:</pre>
#008000">// Create a sanitized input</span></div><div class='line'><span style="color:
#0000FF">let</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='let userInput: string' >userInput</data-lsp></span><span style="color:</pre>

string): UserInputSanitizedString' >sanitizeInput</data-lsp></span><span style="color:
#000000">(</span><span style="color: #795E26"> < data-lsp lsp='function getInput(): string'
>getInput</data-lsp></span><span style="color: #000000">());</span></div> <div
class='line'> < span style="color: #008000">// Can still be re-assigned with a string
though</span></div><div class='line'><span style="color: #001080"><data-lsp lsp='let
userInput: string' >userInput</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #A31515"> "new input" </span> < span style="color: #000000">; </span> </div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEAzArgOzAFwJYHtXwHMQMBJVAB2
c42krMwARNdbgMVoDOEA'>Try</a></div>
```

Interfaces

An *interface declaration* is another way to name an object type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
Point' > Point < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) Point.x: number' >x</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99">number</span><span style="color: #000000">;</span></div>
<div class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-</pre>
lsp lsp='(property) Point.y: number' >y</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99">number</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000">}</span></div> <div class='line'><span
style="color: #0000FF">function</span><span style="color: #000000"> </span><span
style="color: #795E26"> < data-lsp lsp='function printCoord(pt: Point): void' > printCoord < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) pt: Point' >pt</data-lsp></span><span style="color: #000000">: </span><span
style="color: #267F99"> < data-lsp lsp='interface Point' > Point < /data-lsp > </span> < span
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #A31515">"The coordinate&apos;s x value is "</span>
<span style="color: #000000"> + </span><span style="color: #001080"> < data-lsp</pre>
lsp='(parameter) pt: Point' >pt</data-lsp></span><span style="color: #000000">.</span><span
style="color: #001080"> < data-lsp lsp='(property) Point.x: number' > x < /data-lsp > < /span > < span
style="color: #000000">);</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:

<span style="color: #000000">, </span><span style="color: #001080"> < data-lsp lsp='(property)</pre>
Point.y: number' >y </data-lsp>:</span> <span style="color: #000000"> </span> <span
```

 $style = "color: \#098658" > 100 < / span > < span style = "color: \#000000" > \}); < / span > < / div > < / code > < a class = 'playground-link'$

href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgAoHtRmQbwFDLIAeAXMiAK4oHByKHI4VGqpszx3LySMtnKOMRkAlwADO0ANCxtnchc8UA'>Try</div>

Just like when we used a type alias above, the example works just as if we had used an anonymous object type. TypeScript is only concerned with the *structure* of the value we passed to printCoord - it only cares that it has the expected properties. Being concerned only with the structure and capabilities of types is why we call TypeScript a *structurally typed* type system.

Differences Between Type Aliases and Interfaces

Type aliases and interfaces are very similar, and in many cases you can choose between them freely. Almost all features of an interface are available in type, the key distinction is that a type cannot be re-opened to add new properties vs an interface which is always extendable.

< code>Type</code> < code>Type</code> < code>Type</code> interface Animal { name: string }
bear = getBear() bear.name bear.honey </code> Extending a type via intersections <code> type Animal = { name: string }
br/> type Bear = Animal & { honey: Boolean }

 < code> type Animal = { name: string }
 type Bear = Animal & { honey: Boolean }

 < code> interface Window { ts: TypeScriptAPI }

You'll learn more about these concepts in later chapters, so don't worry if you don't understand all of these right away.

- Prior to TypeScript version 4.2, type alias names <u>may appear in error messages</u>, sometimes in place of the equivalent anonymous type (which may or may not be desirable). Interfaces will always be named in error messages.
- Type aliases may not participate in declaration merging, but interfaces can.
- Interfaces may only be used to <u>declare the shapes of object, not re-name primitives</u>.
- Interface names will <u>always appear in their original form</u> in error messages, but *only* when they are used by name.

For the most part, you can choose based on personal preference, and TypeScript will tell you if it needs something to be the other kind of declaration. If you would like a heuristic, use interface

Type Assertions

Sometimes you will have information about the type of a value that TypeScript can't know about.

For example, if you're using document.getElementById, TypeScript only knows that this will return *some* kind of HTMLElement, but you might know that your page will always have an HTMLCanvasElement with a given ID.

In this situation, you can use a type assertion to specify a more specific type:

<div class='code-container' > <code> <div class='line' > const <data-lsp lsp='const myCanvas: HTMLCanvasElement' > myCanvas </data-lsp > <data-lsp lsp='(method) Document.getElementById(elementId: string): HTMLElement | null' > getElementById </data-lsp > (((<data-lsp lsp='interface HTMLCanvasElement' > HTMLCanvasElement </data-lsp >

Like a type annotation, type assertions are removed by the compiler and won't affect the runtime behavior of your code.

You can also use the angle-bracket syntax (except if the code is in a .tsx file), which is equivalent:

<div class='code-container'> <code> <div class='line'> const < <data-lsp lsp='const myCanvas: HTMLCanvasElement' >myCanvas</data-lsp> = < <data-lsp lsp='interface HTMLCanvasElement' > HTMLCanvasElement </data-lsp> <data-lsp lsp='var document: Document' > document </data-lsp> . <data-lsp lsp='(method) Document.getElementById(elementId: string): HTMLElement | null' > getElementById </data-lsp> ("main_canvas" ; </div> </code> <a class='playground-link'</pre>

href='https://www.typescriptlang.org/play/#code/MYewdgzgLgBAtgTwMIEMwDcURgXhgHgAkAVAWQB </div>

Reminder: Because type assertions are removed at compile-time, there is no runtime checking associated with a type assertion. There won't be an exception or null generated if the type assertion is wrong.

TypeScript only allows type assertions which convert to a *more specific* or *less specific* version of a type. This rule prevents "impossible" coercions like:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #00000FF"> const</span> <span style="color: #000000"> </span> <span style="color: #0070C1"> <data-lsp lsp='const x: number' >x</data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #000000"> = </span> <span style="color: #A31515"> "hello" </span> <span style="color: #000000"> </span> <span style="color: #267F99"> number </span> <span style="color: #000000"> ;</span> </div> <span class="error"> <span> Conversion of type 'string' to type 'number' may be a mistake because neither type sufficiently overlaps with the other. If this was intentional, convert the expression to 'unknown' first. </span> <span class="code"> 2352 </span> </span> <span class="error-behind"> Conversion of type 'string' to type 'number' may be a mistake because neither type sufficiently overlaps with the other. If this was intentional, convert the expression to 'unknown' first. </span> </code> <a class='playground-link'</pre>
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYCsaBQBjOAO0QBdQAF </div>

Sometimes this rule can be too conservative and will disallow more complex coercions that might be valid. If this happens, you can use two assertions, first to any (or unknown, which we'll introduce later), then to the desired type:

<div class='code-container'> <code> <div class='line'> const <data-lsp lsp='const a: T' >a </data-lsp> <data-lsp lsp='const expr: any' >expr </data-lsp> any any <data-lsp lsp='type T = {&#13; a: 1;&#13; b: 2;&#13; c: 3;&#13;}' >T </data-lsp > ; </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEYD2A7AzgF3iAHgBxgC54oUBPAbg(</div>

Literal Types

In addition to the general types string and number, we can refer to *specific* strings and numbers in type positions.

One way to think about this is to consider how JavaScript comes with different ways to declare a variable. Both var and let allow for changing what is held inside the variable, and const does not. This is reflected in how TypeScript creates types for literals.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span > < span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='let
changingString: string' > changingString < /data-lsp > </span > < span style="color: #000000" > =
</span><span style="color: #A31515"> "Hello World" </span> < span style="color: #000000">;
</span></div><div class='line'><span style="color: #001080"><data-lsp lsp='let
changingString: string' > changingString < /data-lsp > </span > < span style="color: #000000" > =
</span><span style="color: #A31515"> "OIÃ; Mundo" </span> < span style="color: #000000">;
</span></div><div class='line'><span style="color: #008000">// Because `changingString` can
represent any possible string, that </span> </div> < div class='line'> < span style="color:
#008000">// is how TypeScript describes it in the type system</span></div><div class='line'>
<span style="color: #001080"> <data-lsp lsp='let changingString: string' style='border-bottom:</pre>
solid 2px lightgrey;'>changingString</data-lsp></span><span style="color: #000000">;</span>
</div><span class='popover-prefix'> </span><span class='popover'> <div class='arrow'>
</div>let changingString: string</span> <div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const constantString: &amp;quot;Hello World&amp;quot;' >constantString</data-
lsp></span><span style="color: #000000"> = </span><span style="color: #A31515"> "Hello
World"</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #008000">// Because `constantString` can only represent 1 possible string, it</span>
</div><div class='line'><span style="color: #008000">// has a literal type representation</span>
</div><div class='line'><span style="color: #001080"><data-lsp lsp='const constantString:
"Hello World"' >constantString</data-lsp></span><span style="color:
#000000">;</span></div><span class='popover-prefix'> </span><span class='popover'><div
class='arrow'></div>const constantString: "Hello World"</span></code><a class='playground-
link'
```

href='https://www.typescriptlang.org/play/#code/DYUwLgBAxgFghgOwOYEtkGUwCc1IgXggCIAJEYYAev6IYMZ8hKTkVLT0THKdqupaOvqjYOOTpuYIEIPALla2uSAOEACMru6ePtUBSMHFETFw0XAQwMUgWHDAI</div>

By themselves, literal types aren't very valuable:

```
 < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let </ span> < span
style="color: #000000"> </ span> < span style="color: #001080"> < data-lsp lsp='let x:
& amp;quot; hello& amp;quot; '> x < / data-lsp> </ span> < span style="color: #000000"> : </ span> < span
style="color: #000000"> = </ span> < span</pre>
```

```
style="color: #A31515"> "hello" </span> <span style="color: #000000">;</span> </div> <div class='line'> <span style="color: #008000"> // OK </span> </div> <div class='line'> <span style="color: #001080"> <data-lsp lsp='let x: &amp;quot;hello&amp;quot;' >x </data-lsp> </span> <<span style="color: #000000"> = </span> <span style="color: #A31515"> "hello" </span> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #008000"> // ... </span> </div> <div class='line'> <span style="color: #001080"> <data-err> <data-lsp lsp='let x: &amp;quot;hello&amp;quot;' >x </data-lsp> </data-err> </span> <span style="color: #000000"> = </span> <span style="color: #000000"> = </span> <span style="color: #000000"> ;</span> </div> <span class="error"> <span> Type '"howdy" </span> <span style="color: #000000"> ;</span> </div> <span class="error"> <span> Type '"howdy" is not assignable to type '"hello". </span> <span class="error-behind"> Type '"howdy" is not assignable to type '"hello". </span> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGY1oFABtIAXUAD1QCIALS </div>
```

It's not much use to have a variable that can only have one value!

But by *combining* literals into unions, you can express a much more useful concept - for example, functions that only accept a certain set of known values:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
printText(s: string, alignment: & amp;quot; left" | & amp;quot; right" |
"center"): void' >printText</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) s: string'
>s</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">, </span><span style="color: #001080">
<data-lsp lsp='(parameter) alignment: &amp;quot;left&amp;quot; | &amp;quot;right&amp;quot; |
"center"' >alignment</data-lsp></span><span style="color: #000000">:
</span><span style="color: #A31515">"left"</span><span style="color: #000000"> | </span>
<span style="color: #A31515"> "right" </span> < span style="color: #000000"> | </span> < span</pre>
style="color: #A31515">"center"</span><span style="color: #000000">) {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #008000">// ...</span>
</div><div class='line'><span style="color: #000000">}</span></div><div class='line'><span
style="color: #795E26"> < data-lsp lsp='function printText(s: string, alignment:
"left" | "right" | "center"): void'
>printText</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"Hello, world"</span><span style="color: #000000">, </span><span style="color:
#A31515">"left"</span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #795E26"> < data-lsp lsp='function printText(s: string, alignment:
"left" | "right" | "center"): void'
>printText</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"G'day, mate"</span><span style="color: #000000">, </span><span
style="color: #A31515"> < data-err> &quot;centre&quot; < /data-err> </span> < span style="color:
```

#000000">);</div>Argument of type '"centre"' is not assignable to parameter of type '"left" | "right" | "center"'.2345Argument of type '"centre"' is not assignable to parameter of type '"left" | "right" | "center"'.</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAGYCuAdgMY/</div>

Numeric literal types work the same way:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> compare(a: string, b: string): -1 | 0 | 1' > compare < /data-lsp > < span style = "color: #000000">(<data-lsp lsp='(parameter) a: string' >a</data-lsp>: string, <data-lsp lsp='(parameter) b: string' >b</data-lsp>: string): - 1 | <span</pre> style="color: #098658">0 | 1 {</div><div class='line'> return <data-lsp lsp='(parameter) a: string' >a</data-lsp> === <data-lsp lsp='(parameter) b: string' >b </data-lsp> ? 0 : <data-lsp lsp='(parameter) a: string' >a</data-lsp> > <data-lsp lsp='(parameter) b: string' >b</data-lsp>? 1: -<span</pre> style="color: #098658">1;</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABBOBbADgQwE4FMAUmAXlgM51 </div>

Of course, you can combine these with non-literal types:

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface
< span style="color: #000000"> < span style="color: #267F99"> < data-lsp lsp='interface
Options' > Options < / data-lsp> < / span> < span style="color: #000000"> { < / span> < / div> < div
class='line'> < span style="color: #001080"> < data-lsp
lsp='(property) Options.width: number' > width < / data-lsp> < / span> < span style="color: #001080"> < span style="color: #001080"

```
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F999999
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div><div
class='line'><span style="color: #0000FF">function</span><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='function configure(x: Options |
"auto"): void' >configure</data-lsp></span><span style="color: #000000">
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) x: Options |
"auto"' >x</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='interface Options' > Options < /data-lsp> </span>
<span style="color: #000000"> | </span><span style="color: #A31515"> "auto" </span> < span</pre>
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #008000">// ...</span></div><div class='line'><span style="color:
#000000">}</span></div><div class='line'><span style="color: #795E26"><data-lsp
lsp='function configure(x: Options | & amp;quot;auto"): void' > configure < /data-lsp>
</span><span style="color: #000000">({ </span><span style="color: #001080"> < data-lsp
lsp='(property) Options.width: number' > width < /data-lsp>: < /span > < span style="color:
#000000"> </span><span style="color: #098658">100</span><span style="color: #000000"> });
</span></div><div class='line'><span style="color: #795E26"><data-lsp lsp='function
configure(x: Options | & Damp;quot;auto"): void' > configure < /data-lsp > </span > < span
style="color: #000000">(</span><span style="color: #A31515">"auto"</span><span
style="color: #000000">);</span></div><div class='line'><span style="color: #795E26"><data-
lsp | sp='function configure(x: Options | & amp;quot;auto& amp;quot;): void' > configure < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #A31515"><data-
err>&guot;automatic&guot;</data-err></span><span style="color: #000000">);</span></div>
<span class="error"><span>Argument of type '"automatic"' is not assignable to parameter of type
'Options | "auto".</span><span class="code">2345</span></span><span class="error-
behind">Argument of type '"automatic" is not assignable to parameter of type 'Options | "auto".
</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAJYB2ALjAGY(
</div>
```

There's one more kind of literal type: boolean literals. There are only two boolean literal types, and as you might guess, they are the types true and false. The type boolean itself is actually just an alias for the union true | false.

Literal Inference

When you initialize a variable with an object, TypeScript assumes that the properties of that object might change values later. For example, if you wrote code like this:

#000000"> = { <data-lsp lsp='(property) counter: number' >counter </data-lsp>: 0 }; </div> <div class='line'> if (<data-lsp lsp='const someCondition: boolean' >someCondition</data-lsp>) { </div> <div class='line'> <data-lsp lsp='const obj: {&#13; counter: number;&#13;}' >obj </data-lsp> <data-lsp lsp='(property) counter: number' >counter </data-lsp> <data-lsp lsp='(property) counter: number' >counter </data-lsp> = 1 </div> <div class='line'> </div> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEYD2A7AzgF3mpBbEAwqsAJYYmoBc ALR9gBXDHx5tk6LEhoAreAF54Ab0RIBKDCBjUADPAC+7EgDN4AChz4iKUuVQBKJW3jwp0gHTI1GmPPgE </div>

TypeScript doesn't assume the assignment of 1 to a field which previously had 0 is an error. Another way of saying this is that obj.counter must have the type number, not 0, because types are used to determine both *reading* and *writing* behavior.

The same applies to strings:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const <data-lsp lsp='const reg:</pre> {
 url: string;
 method: string;
}' >reg</data-lsp> = { <data-lsp lsp='(property) url: string' >url </data-lsp>: "https://example.com", < data-lsp lsp='(property) method: string' > method < /data-lsp >: "GET" < span</pre> style="color: #000000"> };</div><div class='line'><data-Isp |sp='function handleRequest(url: string, method: "GET" | "POST"): void' >handleRequest</data-lsp>(<data-lsp lsp='const reg: {&#13; url: string;
 method: string;
}' >reg</data-lsp>.<data-lsp lsp='(property) url: string' >url</data-lsp>, <data-lsp lsp='const reg: {&#13; url: string;&#13; method: string;&#13;}'</pre> >reg</data-lsp>. <data-lsp lsp='(property) method: string' > method</data-lsp> < span style="color:</pre> #000000">);</div>Argument of type 'string' is not assignable to parameter of type '"GET" | "POST"'.2345 Argument of type 'string' is not assignable to parameter of

type '"GET" | "POST"'.</code>Try</div>

In the above example req.method is inferred to be string, not "GET". Because code can be evaluated between the creation of req and the call of handleRequest which could assign a new string like "GUESS" to req.method, TypeScript considers this code to have an error.

There are two ways to work around this.

1. You can change the inference by adding a type assertion in either location:

```
class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color:
#000000"> < div class='code-container' > < code > < div class='line' > < span style="color:
#008000">// Change 1:</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color:
#0070C1"> < data-lsp lsp='const req: {&amp;#13; url: string;&amp;#13; method:
"GET";
}' >req</data-lsp></span><span style="color:
#000000"> = { </span> <span style="color: #001080"> <data-lsp lsp='(property) url: string'
>url</data-lsp>:</span><span style="color: #000000"> </span><span style="color:
#A31515">"https://example.com"</span><span style="color: #000000">, </span><span
style="color: #001080"> < data-lsp lsp='(property) method: & amp;quot;GET& amp;quot;'
>method</data-lsp>:</span><span style="color: #000000"> </span><span style="color:
#A31515">"GET"</span><span style="color: #000000"> </span><span style="color:
#AF00DB">as</span><span style="color: #000000"> </span><span style="color:
#A31515">"GET"</span><span style="color: #000000"> };</span></div><div class='line'>
<span style="color: #008000">// Change 2</span></div><div class='line'><span</pre>
style="color: #795E26"> < data-lsp lsp='function handleRequest(url: string, method:
"GET" | "POST"): void' > handleRequest < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-
lsp lsp='const req: {
 url: string;
 method:
"GET";
}' >req</data-lsp></span><span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property) url: string'
>url</data-lsp></span><span style="color: #000000">, </span><span style="color:
#001080"> < data-lsp lsp='const req: {&amp;#13; url: string;&amp;#13; method:
"GET";
}' >req</data-lsp></span><span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property) method:
"GET"' > method < /data-lsp > </span > < span style="color: #000000" >
</span><span style="color: #AF00DB">as</span><span style="color: #000000"> </span>
<span style="color: #A31515">"GET"</span><span style="color: #000000">);</span>
</div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEAzArgOzAFwJYHtXwAspVglQ/
s27AYSJ8EARjZLMDwGeDgqeABeeABveBZ2dQIMDAAHOjZbEAAPKCFUsqA6YKEpQRExCWI5JXqoC
</div>
```

Change 1 means "I intend for req.method to always have the *literal type* "GET" ", preventing the possible assignment of "GUESS" to that field after. Change 2 means "I know for other reasons that req.method has the value "GET" ".

2. You can use as const to convert the entire object to be type literals:

```
class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color:
#000000"> < div class='code-container' > < code > < div class='line' > < span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color:
#0070C1"> < data-lsp lsp='const req: {&amp;#13; readonly url:
"https://example.com";
 readonly method:
"GET";
}' >req</data-lsp></span><span style="color:
\#000000" = { </span > < span style="color: \#001080" > < data-lsp lsp='(property) url:
"https://example.com"' >url</data-lsp>:</span><span style="color:
#000000"> </span><span style="color: #A31515"> "https://example.com" </span> < span
style="color: #000000">, </span><span style="color: #001080"> <data-lsp lsp='(property)
method: "GET"' >method</data-lsp>:</span><span style="color:
#000000"> </span><span style="color: #A31515">"GET"</span><span style="color:
#000000"> } </span><span style="color: #AF00DB">as</span><span style="color:
#000000"> </span><span style="color: #0000FF"> <data-lsp lsp='any' >const</data-lsp>
</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #795E26"> < data-lsp lsp='function handleRequest(url: string, method:
"GET" | "POST"): void' > handleRequest < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-
Isp Isp='const req: {
 readonly url:
"https://example.com";
 readonly method:
"GET";
}' >req</data-lsp> </span> < span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property) url:
"https://example.com"' >url</data-lsp></span><span style="color:
#000000">, </span><span style="color: #001080"> < data-lsp lsp='const req: {&amp;#13;
readonly url: & amp;quot; https://example.com"; & amp; #13; readonly method:
"GET";
}' >req</data-lsp> </span> < span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property) method:
"GET"' > method < /data-lsp > </span > < span style="color: #000000">);
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxgNghqTiAEAzArgOzAFwJYHtXwAspVqlQ/
uWweBvDhV4AXngAb3gWdnUCDAwABzo2WxAADyghaLIAOk8hKUERMQlpeSV4AF94KDp4T1QG
</div>
```

The as const suffix acts like const but for the type system, ensuring that all properties are assigned the literal type instead of a more general version like string or number.

null and undefined

JavaScript has two primitive values used to signal absent or uninitialized value: null and undefined.

TypeScript has two corresponding *types* by the same names. How these types behave depends on whether you have the strictNullChecks option on.

strictNullChecks off

With strictNullChecks off, values that might be null or undefined can still be accessed normally, and the values null and undefined can be assigned to a property of any type. This is similar to how languages without null checks (e.g. C#, Java) behave. The lack of checking for these values tends to be a major source of bugs; we always recommend people turn strictNullChecks on if it's practical to do so in their codebase.

strictNullChecks on

With strictNullChecks on, when a value is null or undefined, you will need to test for those values before using methods or properties on that value. Just like checking for undefined before using an optional property, we can use *narrowing* to check for values that might be null:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> doSomething(x: string | null): void' >doSomething</data-lsp> < span style="color: #000000">(<data-lsp lsp='(parameter) x: string | null' >x</data-lsp>: string | null) {</div><div class='line'> if (<data-lsp lsp='(parameter) x: string | null' >x</data-lsp> === null) {</div><div class='line'> // do nothing</div> <div class='line'> } <span style="color:</pre> #AF00DB">else {</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> ("Hello, " + <data-lsp</pre>

lsp='(parameter) x: string' >x</data-lsp> . <data-lsp lsp='(method) String.toUpperCase(): string'
>toUpperCase</data-lsp> ()); </div> <div
class='line'> } </div> <div class='line'> } </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAEzgZTgWwKZQBYxgDmAFAB4B
</div>

Non-null Assertion Operator (Postfix!)

TypeScript also has a special syntax for removing null and undefined from a type without doing any explicit checking. Writing! after any expression is effectively a type assertion that the value isn't null or undefined:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> liveDangerously(x?: number | null | undefined): void' > liveDangerously < /data-lsp > (<data-lsp lsp='(parameter) x: number | null | undefined' >x</data-lsp>?: number | null) {</div><div class='line'> // No error</div><div class='line'> < data-lsp lsp='var console: Console' > console < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(< data-lsp lsp='(parameter) x: number | null | undefined' > x < /data-lsp > < /span > < span style="color: #000000">!.<data-lsp lsp='(method) Number.toFixed(fractionDigits?: number | undefined): string' >toFixed</data-lsp>());</div><div class='line'>)</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAGxgNwKYBECGYDmGATnCAM7 </div>

Just like other type assertions, this doesn't change the runtime behavior of your code, so it's important to only use! when you know that the value *can't* be null or undefined.

Enums

Enums are a feature added to JavaScript by TypeScript which allows for describing a value which could be one of a set of possible named constants. Unlike most TypeScript features, this is *not* a

type-level addition to JavaScript but something added to the language and runtime. Because of this, it's a feature which you should know exists, but maybe hold off on using unless you are sure. You can read more about enums in the Enum reference page.

Less Common Primitives

It's worth mentioning the rest of the primitives in JavaScript which are represented in the type system. Though we will not go into depth here.

bigint

From ES2020 onwards, there is a primitive in JavaScript used for very large integers, BigInt:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #008000">// Creating a bigint via the BigInt function</div><div class='line'>const <data-lsp lsp='const oneHundred: bigint' >oneHundred</data-lsp><span style="color:</pre> #000000">: bigint < span style="color: #000000"> = < data-lsp lsp='var BigInt: BigIntConstructor&#13; (value: string | number | bigint | boolean) => bigint' > BigInt < /data-lsp > (1001001#000000">);</div> <div class='line'>// Creating a BigInt via the literal syntax</div><div class='line'>const <data-lsp lsp='const</pre> anotherHundred: bigint' > anotherHundred < /data-lsp > < /span > < span style="color: #000000">: bigint = 100n<span</pre> style="color: #000000">;</div></code>Try</div>

You can learn more about BigInt in the TypeScript 3.2 release notes.

symbol

There is a primitive in JavaScript used to create a globally unique reference via the function Symbol():

```
(description?: string | number | undefined) => symbol < /data-lsp > </span > <span
style="color: #000000">(</span><span style="color: #A31515">"name"</span><span
style="color: #000000">);</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const secondName: typeof secondName' > secondName < /data-lsp > </span> < span
style="color: #000000"> = </span><span style="color: #267F99"> < data-lsp lsp='var Symbol:
SymbolConstructor
(description?: string | number | undefined) => symbol'
>Symbol</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"name"</span><span style="color: #000000">);</span></div> <div class='line'>
<span style="color: #AF00DB">if</span><span style="color: #000000"> (</span><span</pre>
style="color: #001080"> < data-lsp lsp='const firstName: typeof firstName' > firstName < /data-lsp>
<span> <span style="color: #000000"> === </span> <span style="color: #001080"> <data-lsp
lsp='const secondName: typeof secondName' > secondName < /data-lsp > </span > < span
style="color: #000000">) {</span></div><span class="error"><span>This condition will always
return 'false' since the types 'typeof firstName' and 'typeof secondName' have no overlap.</span>
<span class="code">2367</span></span><span class="error-behind">This condition will always
return 'false' since the types 'typeof firstName' and 'typeof secondName' have no overlap.</span>
<div class='line'><span style="color: #000000"> </span><span style="color: #008000">//
Can't ever happen</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYBsB2AUAMZwB2iALqA
</div>
```

You can learn more about them in <u>Symbols reference page</u>.

Narrowing

Imagine we have a function called padLeft.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> padLeft(padding: number | string, input: string): string' > padLeft</data-lsp> < span style="color: #000000">(<data-lsp lsp='(parameter) padding: string | number' > padding < /data-lsp > < span style="color: #000000">: number | <span</pre> style="color: #267F99">string, < data-lsp lsp='(parameter) input: string' > input < /data-lsp> < /span> : string<span</pre> style="color: #000000">): string {</div><div class='line'> throw new <span</pre> style="color: #267F99"> < data-lsp lsp='var Error: ErrorConstructor&#13;new (message?: string | undefined) => Error' > Error < /data-lsp> < /span> < span style="color: #000000"> ("Not implemented yet!" < span style="color: #000000">); </div><div class='line'>}</div></code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABABwIYBMAyBTYUAUa66MYA5gF</div>

If padding is a number, it will treat that as the number of spaces we want to prepend to input. If padding is a string, it should just prepend padding to input. Let's try to implement the logic for when padLeft is passed a number for padding.

class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> <div
class='code-container'> <code> <div class='line'> function
 <data-lsp lsp='function
padLeft(padding: number | string, input: string): string' >padLeft </data-lsp> (<data-lsp lsp='(parameter)
padding: string | number' > padding </data-lsp> : | , <data-lsp lsp='(parameter) input: string' >input </data-lsp> : string ; string ; string ; string ; string ; ; ; </span style="color:

return new <span</pre> style="color: #267F99"> < data-lsp lsp='var Array: ArrayConstructor&#13;new &lt;any> (...items: any[]) => any[] (+2 overloads)' >Array</data-lsp>(<data-lsp lsp='(parameter) padding: string | number' >padding</data-lsp> + 1). < data-lsp lsp='(method) Array&lt;any>.join(separator?: string | undefined): string' >join</data-lsp>(" ") + <data-lsp lsp='(parameter) input: string' >input</data-lsp><span style="color:</pre> #000000">;</div>Operator '+' cannot be applied to types 'string | number' and 'number'.2365Operator '+' cannot be applied to types 'string | number' and 'number'. < div class='line'> < span style="color: #000000">} < /div> < /code> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYBsBWAUAGYCuAdgMY. </div>

Uh-oh, we're getting an error on padding + 1. TypeScript is warning us that adding a number to a number | string might not give us what we want, and it's right. In other words, we haven't explicitly checked if padding is a number first, nor are we handling the case where it's a string, so let's do exactly that.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> padLeft(padding: number | string, input: string): string' > padLeft</data-lsp> < span style="color: #000000">(<data-lsp lsp='(parameter) padding: string | number' > padding < /data-lsp > < span style="color: #000000">: number | <span</pre> style="color: #267F99">string, < data-lsp lsp='(parameter) input: string' > input < /data-lsp> < /span> : string<span</pre> style="color: #000000">) {</div><div class='line'> if (typeof < data-lsp lsp='(parameter) padding: string | number' > padding < /datalsp> === "number") {</div><div class='line'> return<span</pre> style="color: #000000"> new <data-lsp lsp='var Array:

ArrayConstructor
new (arrayLength?: number | undefined) => any[] (+2 overloads)' >Array</data-lsp>(< data-lsp lsp='(parameter) padding: number' > padding < /data-lsp > < span style="color: #000000"> + 1).<data-lsp lsp='(method) Array<any>.join(separator?: string | undefined): string' >join</data-lsp>(" ") + < data-lsp lsp='(parameter) input: string' >input</data-lsp>;</div><div class='line'> }</div><div class='line'> return < data-lsp lsp='(parameter) padding: string' > padding < /data-lsp> + < data-lsp lsp='(parameter) input: string' >input</data-lsp>; </div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABABwIYBMAyBTYUAUa66MYA5gF

</div>
If this mostly looks like uninteresting JavaScript code, that's sort of the point. Apart from the

annotations we put in place, this TypeScript code looks like JavaScript. The idea is that TypeScript's type system aims to make it as easy as possible to write typical JavaScript code without bending over backwards to get type safety.

While it might not look like much, there's actually a lot going under the covers here. Much like how TypeScript analyzes runtime values using static types, it overlays type analysis on JavaScript's runtime control flow constructs like if/else, conditional ternaries, loops, truthiness checks, etc., which can all affect those types.

Within our if check, TypeScript sees typeof padding === "number" and understands that as a special form of code called a *type guard*. TypeScript follows possible paths of execution that our programs can take to analyze the most specific possible type of a value at a given position. It looks at these special checks (called *type guards*) and assignments, and the process of refining types to more specific types than declared is called *narrowing*. In many editors we can observe these types as they change, and we'll even do so in our examples.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < span style="color: #000000"> < span style="color: #795E26"> < data-lsp lsp='function padLeft(padding: number | string, input: string): string' > padLeft < /data-lsp > < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) padding: string | number' > padding < /data-lsp> < span style="color: #000000"> : < span style="color: #000000"> | < span style="color: #000000"> | < span style="color: #267F99"> string < span style="color: #000000"> , < span style="color: #267F99"> string < span style="color: #000000"> , < span style="

style="color: #001080"> < data-lsp lsp='(parameter) input: string' > input < /data-lsp> < /span> : string<span</pre> style="color: #000000">) {</div><div class='line'> if (typeof < data-lsp lsp='(parameter) padding: string | number' > padding < /datalsp> === "number") {</div><div class='line'> return<span</pre> style="color: #000000"> new <data-lsp lsp='var Array: ArrayConstructor
new (arrayLength?: number | undefined) => any[] (+2 overloads)' >Array</data-lsp>(<data-lsp lsp='(parameter) padding: number' style='border-bottom: solid 2px lightgrey;'>padding</data-lsp> + 1). < data-lsp lsp='(method) Array&lt;any>.join(separator?: string | undefined): string' >join</data-lsp>(" ") + <data-lsp lsp='(parameter) input: string' >input</data-lsp><span style="color:</pre> #000000">;</div> <div class='arrow'></div>(parameter) padding: number <div class='line'> } </div> <div class='line'> return < data-lsp lsp='(parameter) padding: string' style='border-bottom: solid 2px lightgrey;'>padding</data-lsp> + < data-lsp lsp='(parameter) input: string' > input < /data-lsp> < /span> ;</div> <span</pre> class='popover'><div class='arrow'></div>(parameter) padding: string <div class='line'>}</div></code>Try</div>

There are a couple of different constructs TypeScript understands for narrowing.

typeof type guards

As we've seen, JavaScript supports a typeof operator which can give very basic information about the type of values we have at runtime. TypeScript expects this to return a certain set of strings:

- "string"
- "number"

- "bigint"
- "boolean"
- "symbol"
- "undefined"
- "object"
- "function"

Like we saw with padLeft, this operator comes up pretty often in a number of JavaScript libraries, and TypeScript can understand it to narrow types in different branches.

In TypeScript, checking against the value returned by typeof is a type guard. Because TypeScript encodes how typeof operates on different values, it knows about some of its quirks in JavaScript. For example, notice that in the list above, typeof doesn't return the string null. Check out the following example:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> printAll(strs: string | string[] | null): void' > printAll < /data-lsp > < /span > < span style="color:</pre> #000000">(<data-lsp lsp='(parameter) strs: string | string[] | null' >strs</data-lsp>: string | string[] | null) {</div><div class='line'> if (typeof<span</pre> style="color: #000000"> <data-lsp lsp='(parameter) strs: string | string[] | null' > strs < /data-lsp > < span style="color: #000000" > === "object") {</div> <div class='line'> <span style="color:</pre> #AF00DB">for (const <data-lsp lsp='const s: string' >s</data-lsp> of <span</pre> style="color: #001080"> < data-err> < data-lsp | sp='(parameter) | strs: string[] | null' > strs < /datalsp></data-err>) {</div> Object is possibly 'null'.2531<span</pre> class="error-behind">Object is possibly 'null'.<div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span>

```
<span style="color: #000000">(</span><span style="color: #001080"> < data-lsp lsp='const s:</pre>
string' >s</data-lsp></span><span style="color: #000000">);</span></div><div class='line'>
<span style="color: #000000"> }</span></div><div class='line'><span style="color: #000000">
} </span> < span style="color: #AF00DB"> else < /span> < span style="color: #000000"> < /span>
<span style="color: #AF00DB">if</span><span style="color: #000000"> (</span><span</pre>
style="color: #0000FF">typeof</span><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(parameter) strs: string' > strs < /data-lsp > </span> < span
style="color: #000000"> === </span><span style="color: #A31515"> "string" </span> < span
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > </span > < span style="color:
#000000">(</span><span style="color: #001080"> < data-lsp lsp='(parameter) strs: string'
>strs</data-lsp></span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #000000"> } </span><span style="color: #AF00DB">else</span><span
style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #008000">// do nothing</span></div><div class='line'><span
style="color: #000000"> }</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMBGAUAGYCuAdgMY
</div>
```

In the printAll function, we try to check if strs is an object to see if it's an array type (now might be a good time to reinforce that arrays are object types in JavaScript). But it turns out that in JavaScript, typeof null is actually "object"! This is one of those unfortunate accidents of history.

Users with enough experience might not be surprised, but not everyone has run into this in JavaScript; luckily, TypeScript lets us know that strs was only narrowed down to string[] | null instead of just string[].

This might be a good seque into what we'll call "truthiness" checking.

Truthiness narrowing

Truthiness might not be a word you'll find in the dictionary, but it's very much something you'll hear about in JavaScript.

In JavaScript, we can use any expression in conditionals, && s, || s, if statements, and Boolean negations (!), and more. As an example, if statements don't expect their condition to always have the type boolean.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> getUsersOnlineMessage(numUsersOnline: number): string' > getUsersOnlineMessage < /data-lsp> (<data-lsp lsp='(parameter) numUsersOnline: number' > numUsersOnline < /data-lsp> < /span> < span style="color: #000000">: number) {</div><div class='line'> if (< data-lsp lsp='(parameter) numUsersOnline: number' >numUsersOnline</data-lsp>) {</div><div class='line'> return `There are < span style="color: #0000FF"> \${ < span style="color: #0000FF"> \${ \${< < data-lsp lsp='(parameter) numUsersOnline: number' > numUsersOnline < /data-lsp> } online now!\';</div><div class='line'> }</div><div class='line'> return "Nobody's here. :(" < span style="color: #000000">; </div><div class='line'>}</div></code>Try</div>

In JavaScript, constructs like if first "coerce" their conditions to boolean s to make sense of them, and then choose their branches depending on whether the result is true or false. Values like

- 0
- NaN

- "" (the empty string)
- On (the bigint version of zero)
- null
- undefined

all coerce to false, and other values get coerced true. You can always coerce values to boolean s by running them through the Boolean function, or by using the shorter double-Boolean negation. (The latter has the advantage that TypeScript infers a narrow literal boolean type true, while inferring the first as type `boolean.)

<div class='code-container'> < code> < div class='line'> < span style="color: #008000">// both of these result in 'true' < /div> < div class='line'> < span style="color: #267F99"> < data-lsp lsp='var Boolean: BooleanConstructor&#13;&lt;string> (value?: string | undefined) => boolean' > Boolean< / data-lsp> < / span> < span style="color: #000000"> (< / span> < span style="color: #000000">); < / span> < span style="color: #000000">, < / span> < span style="color: #008000">// type: true, value: true < / span> < / div> < / code> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAECMHsBcAtUgM1HApgZ1aAThgrgDbSgCWAdqAC < //div>

It's fairly popular to leverage this behavior, especially for guarding against values like null or undefined. As an example, let's try using it for our printAll function.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> printAll(strs: string | string[] | null): void' > printAll < /data-lsp > < span style="color: #000000">(<data-lsp lsp='(parameter) strs: string | string[] | null' >strs</data-lsp>: string | string[] | null) {</div><div class='line'> if (<data-lsp</pre> lsp='(parameter) strs: string | string[] | null' >strs</data-lsp><span style="color:</pre> #000000"> && typeof <data-lsp lsp='(parameter) strs: string | string[]' > strs < /data-lsp > < span style="color: #000000" > = = = < span style="color: #A31515"> "object" < span style="color: #000000">) { </div> < div class='line'> for (const<span</pre> style="color: #000000"> <data-lsp lsp='const s: string' >s</data-lsp> of <data-lsp lsp='(parameter) strs: string[]' >strs</data-lsp>) {</div><div class='line'> <data-lsp lsp='var console: Console' > console </data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(<span style="color: #001080" < data-lsp lsp='const s: string' > s < /data-lsp > < span style="color: #000000" >);

```
</span></div><div class='line'><span style="color: #000000"> }</span></div><div
class='line'><span style="color: #000000"> } </span><span style="color:
#AF00DB">else</span><span style="color: #000000"> </span><span style="color:
#AF00DB">if</span><span style="color: #000000"> (</span><span style="color:
#0000FF">typeof</span><span style="color: #000000"> </span><span style="color: #001080">
 <data-lsp lsp='(parameter) strs: string | null' >strs</data-lsp></span><span style="color:</pre>
#000000"> === </span><span style="color: #A31515"> "string" </span> < span style="color: "#A31515" > "string" </span > < span style="color: "#A31515" > "string" </span style="color: "#A31515" > "string" </span style="color:
#000000">) {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span> < span
style="color: #000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Console.log(...data: any[]): void' >log</data-lsp></span><span style="color: #000000">(</span>
 <span style="color: #001080"> <data-lsp lsp='(parameter) strs: string' > strs </data-lsp> </span>
 <span style="color: #000000">);</span></div><div class='line'><span style="color: #000000">
}</span> </div> < div class='line'> < span style="color: #000000">}</span> </div> </code> < a</pre>
class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABABwE4zFAggGxwCgGcpVCAuRY!
```

</div>

You'll notice that we've gotten rid of the error above by checking if strs is truthy. This at least prevents us from dreaded errors when we run our code like:

```
 < div
class="language-id"> txt < / div > < div class='code-container' > < code > < div class='line' > < span
style="color: undefined"> TypeError: null is not iterable < / span > < / div > < / code > < / div >
```

Keep in mind though that truthiness checking on primitives can often be error prone. As an example, consider a different attempt at writing printAll

```
#000000"> < div class='code-container'> < code> < div class='line dim'> < span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function printAll(strs: string | string[] | null): void' > printAll < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) strs: string | string[] | null' >strs</data-lsp></span><span style="color:</pre>
#000000">: </span> <span style="color: #267F99"> string </span> < span style="color: #000000">
| </span> < span style="color: #267F99"> string </span> < span style="color: #000000">[] |
</span><span style="color: #267F99">null</span><span style="color: #000000">) {</span>
</div><div class='line dim'><span style="color: #000000"> </span><span style="color:
#008000">//!!!!!!!!!!!</span></div><div class='line dim'><span style="color: #000000">
</span><span style="color: #008000">// DON&apos;T DO THIS!</span></div><div class='line
dim'><span style="color: #000000"> </span><span style="color: #008000">// KEEP
READING </span> </div> <div class='line dim'> <span style="color: #000000"> </span> <span
style="color: #008000">//!!!!!!!!!!!</span></div><div class='line dim'><span style="color:
#000000"> </span> <span style="color: #AF00DB">if</span> <span style="color: #000000">
```

```
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) strs: string | string[] | null'
>strs</data-lsp></span><span style="color: #000000">) {</span></div><div class='line dim'>

```

We wrapped the entire body of the function in a truthy check, but this has a subtle downside: we may no longer be handling the empty string case correctly.

TypeScript doesn't hurt us here at all, but this is behavior worth noting if you're less familiar with JavaScript. TypeScript can often help you catch bugs early on, but if you choose to do *nothing* with a value, there's only so much that it can do without being overly prescriptive. If you want, you can make sure you handle situations like these with a linter.

One last word on narrowing by truthiness is that Boolean negations with ! filter out from negated branches.

```

Equality narrowing

TypeScript also uses switch statements and equality checks like === , !== , and != to narrow types. For example:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> example(x: string | number, y: string | boolean): void' > example < /data-lsp > < span style="color: #000000">(<data-lsp lsp='(parameter) x: string | number' >x</data-lsp>: string | number < span style="color: #000000">, < span style="color: #001080"> <data-lsp lsp='(parameter) y: string | boolean' >y </data-lsp> : string<span</pre> style="color: #000000"> | boolean) {</div><div class='line'> if (< data-lsp lsp='(parameter) x: string | number' > x < /data-lsp > < /span> === <data-lsp</pre> lsp='(parameter) y: string | boolean' >y</data-lsp>) {</div><div class='line'> // We can now call any 'string' method on 'x' or 'y'.</div><div class='line'> < data-lsp lsp='(parameter) x: string' > x < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) String.toUpperCase(): string' style='border-bottom: solid 2px lightgrey;'>toUpperCase</data-lsp> ();</div> <div class='arrow'></div>(method) String.toUpperCase(): string <div class='line'> <data-</pre> lsp lsp='(parameter) y: string' >y </data-lsp> < span style="color: #000000">. <data-lsp lsp='(method) String.toLowerCase(): string'</pre> style='border-bottom: solid 2px lightgrey;'>toLowerCase</data-lsp>();</div> <div class='arrow'></div>(method) String.toLowerCase(): string <div class='line'> } else {</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp> .<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(<data-lsp lsp='(parameter) x: string | number' style='border-bottom: solid 2px lightgrey;'>x</data-lsp>); </div> <div

When we checked that x and y are both equal in the above example, TypeScript knew their types also had to be equal. Since string is the only common type that both x and y could take on, TypeScript knows that x and y must be a string in the first branch.

Checking against specific literal values (as opposed to variables) works also. In our section about truthiness narrowing, we wrote a printAll function which was error-prone because it accidentally didn't handle empty strings properly. Instead we could have done a specific check to block out null s, and TypeScript still correctly removes null from the type of strs.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> printAll(strs: string | string[] | null): void' > printAll < /data-lsp > < /span > < span style="color:</pre> #000000">(<data-lsp lsp='(parameter) strs: string | string[] | null' >strs</data-lsp>: string | string[] | null) {</div><div class='line'> if (<data-lsp</pre> lsp='(parameter) strs: string | string[] | null' >strs</data-lsp><span style="color:</pre> #000000">!== null) {</div><div class='line'> if (typeof <data-lsp lsp='(parameter) strs: string | string[]' >strs</data-lsp><span style="color:</pre> #000000"> === "object") {</div><div class='line'> for (const

```
<data-lsp lsp='const s: string' >s</data-lsp></span><span style="color: #000000"> </span>

strs: string</span> <div class='line'><span style="color: #000000"> }</span></div><div
class='line'><span style="color: #000000"> }</span></div><div class='line'><span style="color:
#000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABABwE4zFAggGxwCgGcpVCAuRY!
</div>
```

JavaScript's looser equality checks with == and != also get narrowed correctly. If you're unfamiliar, checking whether something == null actually not only checks whether it is specifically the value null - it also checks whether it's potentially undefined. The same applies to == undefined: it checks whether a value is either null or undefined.

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface

The in operator narrowing

Javascript has an operator for determining if an object has a property with a name: the in operator. TypeScript takes this into account as a way to narrow down potential types.

For example, with the code: "value" in x. where "value" is a string literal and x is a union type. The "true" branch narrows x 's types which have either an optional or required property value, and the "false" branch narrows to types which have an optional or missing property value.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type Fish =</pre> {
 swim: () => void;
}' >Fish</data-lsp> = { <data-lsp lsp='(property) swim: () => void' >swim</data-lsp>: () => void };</div><div class='line'>type < data-lsp lsp='type Bird = {&#13; fly: () => void;&#13;}' > Bird < /data-lsp> = { <data-lsp lsp='(property) fly: () => void' >fly</data-lsp>: () =&qt; <span</pre> style="color: #267F99">void };</div> <div class='line'> < span style="color: #0000FF"> function < / span > < span style="color: #000000"> <data-lsp lsp='function move(animal: Fish | Bird): void' >move</data-lsp>(< data-lsp lsp='(parameter) animal: Fish | Bird' > animal < /data-lsp > < span style="color: #000000">: < data-lsp lsp='type Fish = {
 swim: () => void;
}' >Fish</data-lsp> | < span style="color: #267F99"> < data-lsp lsp='type Bird = {&#13; fly: () => void;
}' > Bird < /data-lsp > < span style = "color: #000000" >) { < /div > <div class='line'> <span style="color:</pre> #AF00DB">if ("swim" in <data-lsp lsp='(parameter) animal: Fish | Bird' > animal </data-lsp > < span style="color:</pre> #000000">) {</div><div class='line'> return < data-lsp lsp='(parameter) animal: Fish' > animal < /data-lsp > .<data-lsp lsp='(property)</pre> swim: () => void' >swim</data-lsp>();</div> <div class='line'> }</div> <div class='line'><span</pre> style="color: #000000"> return <data-lsp lsp='(parameter)

```
animal: Bird' >animal </data-lsp > </span> < span style="color: #000000">.</span> < span style="color: #795E26"> < data-lsp | lsp='(property) | fly: () => void' > fly </data-lsp > </span> < span style="color: #000000">(); </span> </div> < div class='line'> < span style="color: #000000"> (); </span> </div> </div> </dode> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAYglgZwBZQLxQN5QQdzgWwC4oAKASj( </div>
```

To re-iterate optional properties will exist in both sides for narrowing, for example a human could both swim and fly (with the right equipment) and thus should show up in both sides of the in check:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type Fish =</pre>
{

instanceof narrowing

JavaScript has an operator for checking whether or not a value is an "instance" of another value. More specifically, in JavaScript x instanceof Foo checks whether the *prototype chain* of x contains Foo.prototype. While we won't dive deep here, and you'll see more of this when we get into classes, they can still be useful for most values that can be constructed with new .. As you might have guessed, instanceof is also a type guard, and TypeScript narrows in branches guarded by instanceof s.

class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function

```

Assignments

As we mentioned earlier, when we assign to any variable, TypeScript looks at the right side of the assignment and narrows the left side appropriately.

```
 < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span> < span
style="color: #000000"> < / span> < span style="color: #001080"> < data-lsp lsp='let x: string |
number' style='border-bottom: solid 2px lightgrey;'> x < / data-lsp> < / span> < span style="color: #000000"> = < / span> < span style="color: #267F99"> < data-lsp lsp='var Math: Math'
> Math < / data-lsp> < / span> < span style="color: #000000"> . < / span> < span style="color: #795E26"> < data-lsp lsp='(method) Math.random(): number' > random < / data-lsp> < / span> < span</pre>
```

style="color: #000000">() < 0.5? 10: "hello world!";</div> <div class='arrow'></div>let x: string | number < div class='line'> < span style="color: #001080"> < data-lsp lsp='let x: string | number' > x < / data-lsp > < / span > < span style="color: #000000"> = 1; </div> <div class='line'><data-lsp lsp='var console: Console' > console < /data-lsp > . < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp lsp='let x: number' style='border-bottom: solid 2px lightgrey;'>x</data-lsp>);</div> <div class='arrow'></div>let x: number < div class='line'> < span style="color: #001080"> <data-lsp lsp='let x: string | number' >x</data-lsp> = "goodbye!"; </div> <div class='line'><data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp lsp='let x: string' style='border-bottom: solid 2px lightgrey;'>x</data-lsp>);</div> <div class='arrow'></div>let x: string</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/DYUwLgBAHhC8EFkCGYAWA6ATkgdgEwHsBbACgEol/ </div>

Notice that each of these assignments is valid. Even though the observed type of x changed to number after our first assignment, we were still able to assign a string to x. This is because the declared type of x - the type that x started with - is string | number, and assignability is always checked against the declared type.

If we'd assigned a boolean to x, we'd have seen an error since that wasn't part of the declared type.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span> < span style="color: #000000"> < / span> < span style="color: #001080"> < data-lsp lsp='let x: string | number' style='border-bottom: solid 2px lightgrey;'> x< / data-lsp> < / span> < span style="color: #000000"> = </ span> < span style="color: #267F99"> < data-lsp lsp='var Math: Math' > Math < / data-lsp> < / span> < span style="color: #000000"> . < / span> < span style="color: #795E26"> < data-lsp lsp='(method) Math.random(): number' > random < / data-lsp> < / span> < span style="color: #000000"> () & lt; < / span> < span style="color: #098658"> 0.5 < / span> < span style="color: #000000"> ? < / span> < span style="color: #098658"> 10 < / span> < span style="color: #000000"> < span style="color: #098658"> 10 < / span> < span style="color: #000000"> < span style="color: #000000"> ? < / span> < span style="color: #000000"> < span style="col

Control flow analysis

Up until this point, we've gone through some basic examples of how TypeScript narrows within specific branches. But there's a bit more going on than just walking up from every variable and looking for type guards in if s, while s, conditionals, etc. For example

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </ span> < span style="color: #000000"> </ span> < span style="color: #795E26"> < data-lsp lsp='function padLeft(padding: number | string, input: string): string' > padLeft < / data-lsp > < / span> < span style="color: #000000"> (< / span> < span style="color: #001080"> < data-lsp lsp='(parameter) padding: string | number' > padding < / data-lsp> < / span> < span style="color: #000000"> : < / span> < span style="color: #000000"> | < / span> < span style="color: #000000"> | < / span> < span style="color: #267F99"> string < / span> < span style="color: #000000"> , < / span> < span style="color: #001080"> < data-lsp lsp='(parameter) input: string' > input < / data-lsp> < / span>

```
<span style="color: #000000">: </span><span style="color: #267F99">string</span><span</pre>
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #AF00DB">if</span><span style="color: #000000"> (</span><span
style="color: #0000FF">typeof</span><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(parameter) padding: string | number' > padding < /data-
lsp></span><span style="color: #000000"> === </span><span style="color:
#A31515">"number"</span><span style="color: #000000">) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #AF00DB">return</span><span</pre>
style="color: #000000"> </span><span style="color: #0000FF">new</span><span style="color:
#000000"> </span><span style="color: #267F99"> <data-lsp lsp='var Array:
ArrayConstructor
new (arrayLength?: number | undefined) => any[] (+2 overloads)'
>Array</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) padding: number' > padding < /data-lsp > </span> < span
style="color: #000000"> + </span><span style="color: #098658">1</span><span style="color:
#000000">).</span><span style="color: #795E26"><data-lsp lsp='(method)

<span style="color: #001080"> < data-lsp lsp='(parameter) padding: string' > padding < /data-lsp>
</span><span style="color: #000000"> + </span><span style="color: #001080"> < data-lsp
lsp='(parameter) input: string' >input</data-lsp></span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABABwIYBMAyBTYUAUa66MYA5gF
</div>
```

padLeft returns from within its first if block. TypeScript was able to analyze this code and see that the rest of the body (return padding + input;) is *unreachable* in the case where padding is a number. As a result, it was able to remove number from the type of padding (narrowing from string | number to string) for the rest of the function.

This analysis of code based on reachability is called *control flow analysis*, and TypeScript uses this flow analysis to narrow types as it encounters type guards and assignments. When a variable is analyzed, control flow can split off and re-merge over and over again, and that variable can be observed to have a different type at each point.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> < span style="color: #000000"> < / span> < span style="color: #795E26"> < data-lsp lsp='function example(): string | number' > example < / data-lsp > < / span> < span style="color: #000000"> ()

Using type predicates

We've worked with existing JavaScript constructs to handle narrowing so far, however sometimes you want more direct control over how types change throughout your code.

To define a user-defined type guard, we simply need to define a function whose return type is a *type* predicate.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF" > function < / span> <data-lsp lsp='function</pre> isFish(pet: Fish | Bird): pet is Fish' >isFish</data-lsp> (<data-lsp lsp='(parameter) pet: Fish | Bird' >pet</datalsp>: < data-lsp lsp='type Fish = {
 swim: () => void;
}' >Fish</data-lsp> | < span style="color: #267F99"> < data-lsp lsp='type Bird = $\{\&\#13; fly: () => void;\&\#13;}'>Bird</data-lsp>):$ <data-lsp lsp='(parameter) pet: Fish | Bird' >pet</datalsp> is <data-lsp lsp='type Fish =</pre> {
 swim: () => void;
}' >Fish</data-lsp> {</div><div class='line'> return (< data-lsp lsp='(parameter) pet: Fish | Bird' > pet < /data-lsp > < /span> as<span</pre> style="color: #000000"> < data-lsp lsp='type Fish = {
 swim: () => void;
}' >Fish</data-lsp>).<data-lsp lsp='(property) swim: () => void'

>swim</data-lsp>!== <data-lsp lsp='var undefined' >undefined</data-lsp>;</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAYglgZwBZQLxQN5QQdzgWwC4oAKASj(KABaEJUdYBCgjl0DlxMoRDckEkhgV0QUL34hMmJUhIRYDMwOKCgtYB0BUxTLKHVCpLIAOlwCKABCVHR

pet is Fish is our type predicate in this example. A predicate takes the form parameterName is Type, where parameterName must be the name of a parameter from the current function signature.

</div>

Any time isFish is called with some variable, TypeScript will *narrow* that variable to that specific type if the original type is compatible.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Both calls to 'swim' and 'fly' are now okay.</div><div class='line'>let <data-lsp lsp='let pet: Fish | Bird' > pet </data-lsp > < span style="color: #000000"> = < data-lsp lsp='function getSmallPet(): Fish | Bird' >getSmallPet</data-lsp>();</div> <div class='line'>if (< data-lsp lsp='function isFish(pet: Fish | Bird): pet is Fish'</pre> >isFish</data-lsp>(<data-lsp lsp='let pet: Fish | Bird' > pet </data-lsp >)) {</div><div class='line'> < data-lsp lsp='let pet: Fish' > pet < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(property) swim: () => void' >swim</data-lsp>();</div><div class='line'> } else<span</pre> style="color: #000000"> {</div><div class='line'> <data-lsp lsp='let pet: Bird' >pet</data-lsp> .<data-lsp lsp='(property)</pre> fly: () => void' >fly</data-lsp>();</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAYglgZwBZQLxQN5QQdzgWwC4oAKASj(EJkxBHBCLDRmBxQUFrAOgKm4ZZQ6imhZAB0uARQAISo6PrKonB6EL4cLBwA9J1QALT9KjrAb1dPbx0wCgqduIpwHRQAOSV+EtFesxLEiDrmtB6dDhQdADW6iBIHOKFSegW1rb2TsDknBxwoqQh0QXA </div>

Notice that TypeScript not only knows that pet is a Fish in the if branch; it also knows that in the else branch, you don't have a Fish, so you must have a Bird.

You may use the type guard isFish to filter an array of Fish | Bird and obtain an array of Fish:

```
 < div</pre>

In addition, classes can <u>use this is Type</u> to narrow their type.

Discriminated unions

Most of the examples we've looked at so far have focused around narrowing single variables with simple types like string, boolean, and number. While this is common, most of the time in JavaScript we'll be dealing with slightly more complex structures.

For some motivation, let's imagine we're trying to encode shapes like circles and squares. Circles keep track of their radiuses and squares keep track of their side lengths. We'll use a field called kind to tell which shape we're dealing with. Here's a first attempt at defining Shape.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
Shape' > Shape < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
Isp='(property) Shape.kind: & amp;quot;circle" | & amp;quot;square"
>kind</data-lsp></span><span style="color: #000000">: </span><span style="color:
#A31515">"circle"</span><span style="color: #000000"> | </span><span style="color:
#A31515">"square"</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)</pre>
Shape.radius?: number | undefined' > radius < /data-lsp > </span > < span style="color: #000000">?:
</span><span style="color: #267F99">number</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(property) Shape.sideLength?: number | undefined' > sideLength < /data-lsp>
</span><span style="color: #000000">?: </span><span style="color:
#267F99">number</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000">}</span></div></code><a class='playground-link'</pre>
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMoAs4AcUG8BQyyA1qACYB
</div>
```

Notice we're using a union of string literal types: "circle" and "square" to tell us whether we should treat the shape as a circle or square respectively. By using "circle" | "square" instead of string, we can avoid misspelling issues.

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function <data-lsp lsp='function handleShape(shape: Shape): void' > handleShape</data-lsp> <(span> <data-lsp lsp='(parameter) shape: Shape' >shape</data-lsp> : : ((< ((<data-lsp lsp='(parameter) shape: Shape' >shape </data-lsp lsp='(property) Shape.kind: &quot;circle&quot; | &quot;square&quot; > kind </data-lsp> (<span

condition will always return 'false' since the types '"circle" | "square" and '"rect" have no overlap.

2367This condition
will always return 'false' since the types '"circle" | "square" and '"rect" have no overlap.

<div class='line'> // ...

</div><div class='line'> }</div><div class='line'> }</div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYBsB2AUAJYB2ALjAGYC

</div>

We can write a getArea function that applies the right logic based on if it's dealing with a circle or square. We'll first try dealing with circles.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> getArea(shape: Shape): number' > getArea < /data-lsp> < /span> < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) shape: Shape' > shape < /datalsp>: < data-lsp lsp='interface Shape' > Shape < /data-lsp > < span style="color: #000000" >) { </div><div class='line'> return <data-lsp lsp='var Math: Math' > Math</data-lsp>.<datalsp lsp='(property) Math.Pl: number' >PI</data-lsp> * < span style="color: #001080"> <data-lsp lsp='(parameter) shape: Shape' >shape</data-lsp><span style="color:</pre> #000000">.<data-lsp lsp='(property) Shape.radius?: number | undefined' >radius </data-lsp> ** 2;</div><span</pre> class="error"> < span > Object is possibly 'undefined'. < / span > < span class="code" > 2532 < / span > Object is possibly 'undefined'.<div class='line'> }</div></code><a class='playground-link'</pre> href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMaBQBLAOwBcYAzAC WhaAUA'>Try</div> <!-- TODO -->

Under strictNullChecks that gives us an error - which is appropriate since radius might not be defined. But what if we perform the appropriate checks on the kind property?

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < span style="color: #000000"> < span style="color: #795E26"> < data-lsp lsp='function getArea(shape: Shape): number | undefined' > getArea < /data-lsp > < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) shape: Shape' > shape < /data-lsp > < span style="color: #000000">: < span style="color: #267F99"> < data-lsp lsp='interface Shape' > Shape < /data-lsp> < /span> < span style="color: #000000"> (< /div> < div class='line'> < span style="color: #000000"> < /span> < span style="color: #000000"> < /span> < span < span < span < span < s

behind">Object is possibly 'undefined'.</span><div class='line'><span style="color: #000000"> }
</span></div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMaBQBLAOwBcYAzAC
</div>
```

Hmm, TypeScript still doesn't know what to do here. We've hit a point where we know more about our values than the type checker does. We could try to use a non-null assertion (a ! after shape.radius) to say that radius is definitely present.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> getArea(shape: Shape): number | undefined' > getArea < /data-lsp > < span style="color: #000000">(<data-lsp lsp='(parameter) shape: Shape' >shape</data-lsp>: < data-lsp lsp='interface Shape' > Shape < /data-lsp > < span style="color: #000000">) {</div><div class='line'> if (< data-lsp lsp='(parameter) shape: Shape' > shape < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(property) Shape.kind: & amp;quot;circle" | & amp;quot;square"' > kind < /data-lsp> === "circle") {</div><div class='line'> return <data-lsp lsp='var Math: Math' > Math </datalsp>.<data-lsp lsp='(property) Math.Pl: number' >PI</data-lsp> * < data-lsp lsp='(parameter) shape:

```
Shape' >shape</data-lsp></span><span style="color: #000000">.</span><span style="color: #001080">.</span><span style="color: #001080"><data-lsp lsp='(property) Shape.radius?: number | undefined' >radius</data-lsp>
</span><span style="color: #000000">! ** </span><span style="color: #098658">2</span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div><div class='line'><span style="color: #000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMoAs4AcUG8BQyyA1qACYBDF4gEYYAB7EGQDCDAAQUE4AApOTBwqDGwIAEpkAiJgGGQ4hlgAOIIQMmQAXgqaOgZmanTMojFw3ic
```

But this doesn't feel ideal. We had to shout a bit at the type-checker with those non-null assertions (!) to convince it that shape.radius was defined, but those assertions are error-prone if we start to move code around. Additionally, outside of strictNullChecks we're able to accidentally access any of those fields anyway (since optional properties are just assumed to always be present when reading them). We can definitely do better.

</div>

The problem with this encoding of Shape is that the type-checker doesn't have any way to know whether or not radius or sideLength are present based on the kind property. We need to communicate what *we* know to the type checker. With that in mind, let's take another swing at defining Shape.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> Circle' > Circle</data-lsp> {</div><div class='line'> < span style="color: #000000"> < span style="color: #001080"> < data-lsp lsp='(property) Circle.kind: "circle"' >kind</data-lsp>: "circle";</div><div class='line'> < span style="color: #001080"> < data-lsp lsp='(property) Circle.radius: number' >radius</data-lsp>: number;</div><div class='line'> }</div> <div class='line'><span style="color:</pre> #0000FF">interface < data-lsp lsp='interface Square' > Square < /data-lsp> < /span> < span style="color: #000000"> { </div> <div class='line'> < data-lsp lsp='(property) Square.kind: & amp;quot;square& amp;quot;' >kind</data-lsp>: "square";</div><div class='line'> <data-lsp lsp='(property)</pre> Square.sideLength: number' > sideLength < /data-lsp> < /span> < span style="color: #000000">: number; </div><div class='line'>}</div> <div class='line'><span

style="color: #0000FF">type <data-lsp lsp='type Shape = Circle | Square' >Shape</data-lsp> = <data-lsp lsp='interface Circle' >Circle</data-lsp> | <data-lsp lsp='interface Square' >Square</data-lsp> ; </span

Here, we've properly separated Shape out into two types with different values for the kind property, but radius and sideLength are declared as required properties in their respective types.

Let's see what happens here when we try to access the radius of a Shape.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> getArea(shape: Shape): number' > getArea < /data-lsp> < /span> < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) shape: Shape' > shape < /datalsp>: < data-lsp lsp='type Shape = Circle | Square' > Shape < /data-lsp> < /span> < span style="color: #000000">) {</div><div class='line'> return <data-lsp lsp='var Math: Math' >Math</data-lsp>.<data-</pre> lsp lsp='(property) Math.Pl: number' >PI</data-lsp> * <data-lsp lsp='(parameter) shape: Shape' > shape/data-lsp><span style="color:</pre> #000000">.<data-err><data-lsp lsp='any' >radius</datalsp></data-err> ** 2;</div> Property 'radius' does not exist on type 'Shape'. Property 'radius' does not exist on type 'Square'.2339Property 'radius' does not exist on type 'Shape'. Property 'radius' does not exist on type 'Square'. <div class='line'>}</div></code><a class='playground-</pre> link'

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQBLAOwBcYAzACtoukA'>Try</div>

Like with our first definition of Shape, this is still an error. When radius was optional, we got an error (only in strictNullChecks) because TypeScript couldn't tell whether the property was present. Now that Shape is a union, TypeScript is telling us that shape might be a Square, and Square s don't have radius defined on them! Both interpretations are correct, but only does our new encoding of Shape still cause an error outside of strictNullChecks.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> getArea(shape: Shape): number | undefined' > getArea < /data-lsp > < span style="color: #000000">(<data-lsp lsp='(parameter) shape: Shape' >shape</data-lsp>: < data-lsp lsp='type Shape = Circle | Square' > Shape < /data-lsp > < span style="color: #000000">) {</div><div class='line'> if (< data-lsp lsp='(parameter) shape: Shape' > shape < /data-lsp > . <data-lsp lsp='(property)</pre> kind: & amp; quot; circle & amp; quot; | & amp; quot; square & amp; quot; '> kind < / data-lsp > < / span> === "circle") {</div><div class='line'> return < data-lsp lsp='var Math: Math' > Math < /data-lsp > < span</pre> style="color: #000000">.<data-lsp lsp='(property) Math.Pl: number' >PI</data-lsp> * < data-lsp lsp='(parameter) shape: Circle' style='border-bottom:</pre> solid 2px lightgrey;'>shape</data-lsp>. < data-lsp lsp='(property) Circle.radius: number' > radius < /data-lsp> ** 2 ;</div> <span</pre> class='popover'> < div class='arrow'> </div> (parameter) shape: Circle < div class='line'> }</div><div class='line'>} </div></code>Try</div>

That got rid of the error! When every type in a union contains a common property with literal types, TypeScript considers that to be a *discriminated union*, and can narrow out the members of the union.

In this case, kind was that common property (which is what's considered a *discriminant* property of Shape). Checking whether the kind property was "circle" got rid of every type in Shape that didn't have a kind property with the type "circle". That narrowed shape down to the type Circle.

The same checking works with switch statements as well. Now we can try to write our complete getArea without any pesky! non-null assertions.

<div class='code-container'><code><div class='line'>function

```

The important thing here was the encoding of Shape. Communicating the right information to TypeScript - that Circle and Square were really two separate types with specific kind fields - was crucial. Doing that let us write type-safe TypeScript code that looks no different than the

JavaScript we would've written otherwise. From there, the type system was able to do the "right" thing and figure out the types in each branch of our switch statement.

As an aside, try playing around with the above example and remove some of the return keywords. You'll see that type-checking can help avoid bugs when accidentally falling through different clauses in a Switch statement.

Discriminated unions are useful for more than just talking about circles and squares. They're good for representing any sort of messaging scheme in JavaScript, like when sending messages over the network (client/server communication), or encoding mutations in a state management framework.

The never type

When narrowing, you can reduce the options of a union to a point where you have removed all possibilities and have nothing left. In those cases, TypeScript will use a never type to represent a state which shouldn't exist.

Exhaustiveness checking

The never type is assignable to every type; however, no type is assignable to never (except never itself). This means you can use narrowing and rely on never turning up to do exhaustive checking in a switch statement.

For example, adding a default to our getArea function which tries to assign the shape to never will raise when every possible case has not been handled.

<div class='code-container'> <code> <div class='line'> type <data-lsp lsp='type Shape = Circle | Square' > Shape </data-lsp lsp='interface Circle' > Circle </data-lsp> <data-lsp lsp='interface Circle' > Circle </data-lsp lsp='interface Square' > Square </data-lsp> <data-lsp lsp='interface Square' > Square </data-lsp> ; </div> <div class='line'> function <data-lsp lsp='function getArea(shape: Shape): number'> getArea </data-lsp> <data-lsp lsp='(parameter) shape: Shape' > shape </data-lsp | sp='type Shape = Circle | Square' > Shape </data-lsp | sp='type Shape = Circle | Square' > Shape </data-lsp> ((((((

More on Functions

Functions are the basic building block of any application, whether they're local functions, imported from another module, or methods on a class. They're also values, and just like other values, TypeScript has many ways to describe how functions can be called. Let's learn about how to write types that describe functions.

Function Type Expressions

The simplest way to describe a function is with a *function type expression*. These types are syntactically similar to arrow functions:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> greeter(fn: (a: string) => void): void' > greeter < / data-lsp > < / span > < span style="color: #000000" > (< span style="color: #795E26"> < data-lsp lsp='(parameter) fn: (a: string) => void' >fn</data-lsp>: (<data-lsp lsp='(parameter) a: string' >a</data-lsp>: string) =&qt; <span</pre> style="color: #267F99">void) {</div><div class='line'> <data-lsp lsp='(parameter) fn: (a: string) => void' >fn</data-lsp> ("Hello, World"); </div><div class='line'>}</div> <div class='line'>function <data-lsp lsp='function printToConsole(s: string): void' >printToConsole</data-lsp>(< data-lsp lsp='(parameter) s: string' > s < /data-lsp > < /span > < span style="color: #000000">: string string string string string string string string) {</div><div class='line'> <data-lsp lsp='var console: Console' > console </data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp> (< data-lsp lsp='(parameter) s: string' > s < /data-lsp > < span</pre> style="color: #000000">);</div><div class='line'>} </div> <div class='line'><data-lsp lsp='function greeter(fn: (a: string) => void): void' > greeter < / data-lsp > </ span > < span style = "color: #000000" > (<data-lsp lsp='function printToConsole(s: string): void'

>printToConsole</data-lsp>);</div></code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAcwE4FN1XagFMMALkVwENiBn </div>

The syntax (a: string) => void means "a function with one parameter, named a, of type string, that doesn't have a return value". Just like with function declarations, if a parameter type isn't specified, it's implicitly any.

Note that the parameter name is **required**. The function type (string) => void means "a function with a parameter named string of type any "!

Of course, we can use a type alias to name a function type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
GreetFunction = (a: string) => void' > GreetFunction < /data-lsp > </span > < span style = "color:
#000000"> = (</span> <span style="color: #001080"> <data-lsp lsp='(parameter) a: string'
>a</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">) </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color:
#267F99">void</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #0000FF">function</span><span style="color: #000000"> </span><span
style="color: #795E26"> < data-lsp lsp='function greeter(fn: GreetFunction): void' > greeter < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) fn: GreetFunction' >fn</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99"><data-lsp lsp='type GreetFunction = (a: string) => void'
>GreetFunction</data-lsp></span><span style="color: #000000">) {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #008000">// ...</span>
</div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBA4gThCwBiBXAdgY2ASwPbpQC8UAFAIYE
</div>
```

Call Signatures

In JavaScript, functions can have properties in addition to being callable. However, the function type expression syntax doesn't allow for declaring properties. If we want to describe something callable with properties, we can write a *call signature* in an object type:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type</pre> DescribableFunction = {
 (someArg: number): boolean;
 description: string;
}' > DescribableFunction < /data-lsp > < span style = "color: #000000" > = {</div><div class='line'> < data-lsp lsp='(property) description: string' > description < /data-lsp > < span style="color: #000000">: string;</div><div class='line'> (<data-lsp lsp='(parameter) someArg: number' >someArg</data-lsp>: number): boolean;</div><div class='line'> };</div><div class='line'><span style="color:</pre> #0000FF">function < data-lsp lsp='function doSomething(fn: DescribableFunction): void' >doSomething</data-lsp>(< data-lsp lsp='(parameter) fn: DescribableFunction' > fn < /data-lsp > < /span > < span style="color: #000000">: < span style="color: #267F99"> < data-lsp lsp='type DescribableFunction = {
 (someArg: number): boolean;
 description: string;
}' > DescribableFunction < /data-lsp> < /span > < span style="color: #000000">) {</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp> .<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(< data-lsp lsp='(parameter) fn: DescribableFunction' > fn < /data-lsp > < /span > < span style="color: #000000">.<data-lsp lsp='(property) description: string' >description</data-lsp> + " returned " + < data-lsp lsp='(parameter) fn: (someArg: number) => boolean' >fn</data-lsp>(6));</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAIhDOBjATgSwEYEN0BsIDEBXAO0WFQHt </div>

Note that the syntax is slightly different compared to a function type expression - use : between the parameter list and the return type rather than => .

Construct Signatures

JavaScript functions can also be invoked with the new operator. TypeScript refers to these as constructors because they usually create a new object. You can write a construct signature by adding the new keyword in front of a call signature:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
SomeConstructor = new (s: string) => SomeObject' >SomeConstructor</data-lsp></span><span
style="color: #000000"> = {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #0000FF">new</span><span style="color: #000000"> (</span>
<span style="color: #001080"> < data-lsp lsp='(parameter) s: string' > s < /data-lsp > </span> < span</pre>
style="color: #000000">: </span><span style="color: #267F99">string</span><span
style="color: #000000">): </span><span style="color: #267F99"> < data-lsp lsp='type SomeObject
= any' >SomeObject</data-lsp></span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000">};</span></div><div class='line'><span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function fn(ctor: SomeConstructor): any' > fn < /data-lsp > </span> < span
style="color: #000000">(</span><span style="color: #001080"> < data-lsp lsp='(parameter) ctor:
SomeConstructor' >ctor </data-lsp> </span> <span style="color: #000000">: </span> <span
style="color: #267F99"> < data-lsp lsp='type SomeConstructor = new (s: string) => any'
>SomeConstructor</data-lsp></span><span style="color: #000000">) {</span></div><div
class='line'> < span style="color: #000000"> </span> < span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#0000FF">new</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='(parameter) ctor: new (s: string) => any' >ctor</data-lsp></span><span
style="color: #000000">(</span><span style="color: #A31515">"hello"</span><span
style="color: #000000">);</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAyg9gWwgeQEYCsIGNhQLxQCGAdiANw
</div>
```

Some objects, like JavaScript's Date object, can be called with or without new. You can combine call and construct signatures in the same type arbitrarily:

```
(</span> <span style="color: #001080"> <data-lsp lsp='(parameter) n: number | undefined'
>n</data-lsp> </span> <span style="color: #000000">?: </span> <span style="color:
#267F99"> number </span> <span style="color: #000000">): </span> <span style="color:
#267F99"> number </span> <span style="color: #000000">; </span> </div> <div class='line'>
<span style="color: #000000">} </span> </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMJwDYYPJVQexAGcwoBXBM
</div>
```

Generic Functions

It's common to write a function where the types of the input relate to the type of the output, or where the types of two inputs are related in some way. Let's consider for a moment a function that returns the first element of an array:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </ span> < span style="color: #000000"> </ span> < span style="color: #795E26"> < data-lsp lsp='function firstElement(arr: any[]): any' > firstElement < / data-lsp > </ span> < span style="color: #000000"> (</ span> < span style="color: #001080"> < data-lsp lsp='(parameter) arr: any[]' > arr < / data-lsp> </ span> < span style="color: #000000">: </ span> < span style="color: #267F99"> any </ span> </ span> < span style="color: #000000">: </ span> < div > < div class='line'> < span style="color: #00000"> (*span> < span style="color: #0000B"> return </ span> < span style="color: #00000"> </ span> < span style="color: #001080"> < data-lsp lsp='(parameter) arr: any[]' > arr < / data-lsp> </ span> < span style="color: #000000"> [</ span> < span style="color: #000000"> | </ span> < span style="col
```

This function does its job, but unfortunately has the return type any . It'd be better if the function returned the type of the array element.

In TypeScript, *generics* are used when we want to describe a correspondence between two values. We do this by declaring a *type parameter* in the function signature:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </span> < span style="color: #000000"> </span> < span style="color: #795E26"> < data-lsp lsp='function firstElement&amp;lt;Type> (arr: Type[]): Type' > firstElement < /data-lsp> </span> < span style="color: #000000"> & lt; </span> < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in firstElement&amp;lt;Type> (arr: Type[]): Type' > Type < /data-lsp lsp='(parameter) arr: Type[]' > arr < /data-lsp> < /span> < span style="color: #001080"> < data-lsp lsp='(parameter) arr: Type[]' > arr < /data-lsp> < /span> < span style="color: #267F99"> </span> < span style="color: #267F99"> </span style="color: #267F99"> </span style="color: #267F999"> </span style="color
```

```
<data-lsp lsp='(type parameter) Type in firstElement&amp;lt;Type>(arr: Type[]): Type'
>Type</data-lsp> </span> <span style="color: #000000">[]): </span> <span style="color:
#267F99"> <data-lsp lsp='(type parameter) Type in firstElement&amp;lt;Type>(arr: Type[]): Type'
>Type</data-lsp> </span> <span style="color: #000000"> {</span> </div> <div class='line'>
<span style="color: #000000"> </span> <span style="color: #AF00DB"> return </span> <span style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) arr:
Type[]' >arr </data-lsp> </span> <span style="color: #000000">[</span> <span style="color: #000000">[</span> <span style="color: #098658"> 0 </span> <span style="color: #000000">];</span> </div> <div class='line'> <span style="color: #000000"> }</span> </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABMGAnAzlAogGwKYC2eYUAPACo
</div>
```

By adding a type parameter Type to this function and using it in two places, we've created a link between the input of the function (the array) and the output (the return value). Now when we call it, a more specific type comes out:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000">// s is of type
'string'</span></div><div class='line'><span style="color: #0000FF">const</span>
<span style="color: #000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const s:</pre>
string' >s</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#795E26"> < data-lsp lsp='function firstElement&amp;lt;string>(arr: string[]): string'
>firstElement</data-lsp></span><span style="color: #000000">([</span><span style="color:
#A31515">"a"</span><span style="color: #000000">, </span><span style="color:
#A31515">"b"</span><span style="color: #000000">, </span><span style="color:
#A31515">"c"</span><span style="color: #000000">]);</span></div><div class='line'><span
style="color: #008000">// n is of type 'number'</span></div><div class='line'>
<span style="color: #0000FF">const</span><span style="color: #000000"> </span><span</pre>
style="color: #0070C1"> < data-lsp lsp='const n: number' > n < /data-lsp> < /span> < span
style="color: #000000"> = </span><span style="color: #795E26"> < data-lsp lsp='function
firstElement<number>(arr: number[]): number' > firstElement</data-lsp> </span> < span
style="color: #000000">([</span><span style="color: #098658">1</span><span style="color:
#000000">, </span><span style="color: #098658">2</span><span style="color: #000000">,
</span> < span style="color: #098658"> 3 < /span> < span style="color: #000000">]); < /span>
</div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxqNqhqTiAEAzArqOzAFwJYHtVKxqGcMBRCEAW
</div>
```

Inference

Note that we didn't have to specify Type in this sample. The type was *inferred* - chosen automatically - by TypeScript.

We can use multiple type parameters as well. For example, a standalone version of map would look like this:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
map<Input, Output>(arr: Input[], func: (arg: Input) => Output): Output[]' >map</data-lsp>
</span><span style="color: #000000">&lt;</span><span style="color: #267F99"><data-lsp
lsp='(type parameter) Input in map<Input, Output>(arr: Input[], func: (arg: Input) =>
Output): Output[]' > Input < /data-lsp > </span > <span style="color: #000000">, </span > <span
style="color: #267F99"> < data-lsp lsp='(type parameter) Output in map&amp;lt;lnput, Output>(arr:
Input[], func: (arg: Input) => Output): Output[]' >Output//data-lsp></span><span style="color:</pre>
#000000">>(</span><span style="color: #001080"><data-lsp lsp='(parameter) arr: Input[]'
>arr</data-lsp></span><span style="color: #000000">: </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Input in map&amp;lt;Input, Output>(arr: Input[], func: (arg: Input)
=> Output): Output[]' >Input</data-lsp></span><span style="color: #000000">[], </span><span
style="color: #795E26" > < data-lsp lsp='(parameter) func: (arg: Input) = > Output' > func < /data-lsp >
</span><span style="color: #000000">: (</span><span style="color: #001080"><data-lsp
lsp='(parameter) arg: Input' >arg</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Input in map&amp;lt;Input,</pre>
Output>(arr: Input[], func: (arg: Input) => Output): Output[]' >Input</data-lsp></span><span
style="color: #000000">) </span><span style="color: #0000FF">=&gt;</span><span
style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='(type parameter)
Output in map<Input, Output>(arr: Input[], func: (arg: Input) => Output): Output[]'
>Output</data-lsp></span><span style="color: #000000">): </span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Output in map&amp;lt;lnput, Output>(arr: lnput[], func:
(arg: Input) => Output): Output[]' >Output</data-lsp></span><span style="color: #000000">[]
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(parameter) arr: Input[]' > arr < /data-lsp> < /span> < span style="color:
#000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Array<Input>.map&amp;lt;Output>(callbackfn: (value: Input, index: number, array: Input[])
=> Output, thisArg?: any): Output[]' >map</data-lsp></span><span style="color: #000000">
(</span><span style="color: #001080"><data-lsp lsp='(parameter) func: (arg: Input) => Output'
>func</data-lsp></span><span style="color: #000000">);</span></div><div class='line'>
<span style="color: #000000">}</span></div> <div class='line'><span style="color:</pre>
#008000">// Parameter 'n' is of type 'string'</span></div><div
class='line'><span style="color: #008000">// &apos;parsed&apos; is of type
'number[]'</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const parsed: number[]' >parsed</data-lsp></span><span style="color:</pre>
#000000"> = </span><span style="color: #795E26"> < data-lsp lsp='function map&amp;lt;string,
number>(arr: string[], func: (arg: string) => number): number[]' >map</data-lsp></span><span
```

style="color: #000000">(["1", "2", "3"], (<data-lsp lsp='(parameter) n: string'>n</data-lsp>)) => <data-lsp lsp='function parseInt(string: string, radix?: number | undefined): number' >parseInt</data-lsp> (<data-lsp lsp='(parameter) n: string'>n</data-lsp>);</data-lsp lsp='(parameter) n: string'>n</data-lsp>);</data-lsp lsp='(parameter) n: string'>n</data-lsp>);</data-lsp lsp='(parameter) n: string'>n</data-lsp>);</data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></data-lsp></dd>

href='https://www.typescriptlang.org/play/#code/PTAEAcCcFMBdYJbUgWgQcwHYHsYCgAzAV0wGNFtN </div>

Note that in this example, TypeScript could infer both the type of the Input type parameter (from the given string array), as well as the Output type parameter based on the return value of the function expression (number).

Constraints

We've written some generic functions that can work on *any* kind of value. Sometimes we want to relate two values, but can only operate on a certain subset of values. In this case, we can use a *constraint* to limit the kinds of types that a type parameter can accept.

Let's write a function that returns the longer of two values. To do this, we need a length property that's a number. We *constrain* the type parameter to that type by writing an extends clause:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> longest<Type extends {&#13; length: number;&#13;}>(a: Type, b: Type): Type' >longest</data-lsp>< < data-lsp lsp='(type parameter) Type in longest&lt;Type extends {&#13; length: number;
}>(a: Type, b: Type): Type' >Type</data-lsp> extends { < span style="color: #001080"> < data-lsp lsp='(property) length: number' >length</data-lsp>: number }>(< data-lsp lsp='(parameter) a: Type extends { length: number; }' > a < /data-lsp > < /span> : < data-lsp lsp='(type)</pre> parameter) Type in longest<Type extends {&#13; length: number;&#13;}>(a: Type, b: Type): Type' > Type</data-lsp>, < data-lsp lsp='(parameter) b: Type extends { length: number; }' > b < /datalsp>: < data-lsp

```
lsp='(type parameter) Type in longest<Type extends {&amp;#13; length:
number;
}>(a: Type, b: Type): Type' >Type</data-lsp></span><span style="color:
#000000">) {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #AF00DB">if</span><span style="color: #000000"> (</span><span style="color:
#001080"> < data-lsp lsp='(parameter) a: Type extends { length: number; }' > a < /data-lsp > < /span>
<span style="color: #000000">.</span><span style="color: #001080"><data-lsp lsp='(property)</pre>
length: number' > length < /data-lsp> < /span> < span style="color: #000000" > &gt;= < /span> < span
style="color: #001080"> < data-lsp lsp='(parameter) b: Type extends { length: number; }' > b < /data-
lsp></span><span style="color: #000000">.</span><span style="color: #001080"><data-lsp
lsp='(property) length: number' >length</data-lsp></span><span style="color: #000000">)
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(parameter) a: Type extends { length: number; }' > a < /data-lsp > < /span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000"> }
</span><span style="color: #AF00DB">else</span><span style="color: #000000"> {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(parameter) b: Type extends { length: number; }' > b < /data-lsp > < /span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000"> }
</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #008000">// longerArray is of type &apos;number[]&apos;
</span></div><div class='line'><span style="color: #0000FF">const</span><span style="color:
#000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const longerArray: number[]'
>longerArray</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#795E26"> < data-lsp lsp='function longest&amp;lt;number[] > (a: number[], b: number[]): number[]'
>longest</data-lsp></span><span style="color: #000000">([</span><span style="color:
#098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">], [</span><span style="color:
#098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">, </span><span style="color:
#098658">3</span><span style="color: #000000">1);</span></div><div class='line'><span
style="color: #008000">// longerString is of type 'string'</span></div><div
class='line'> < span style="color: #0000FF"> const < / span > < span style="color: #000000"> < / span>
<span style="color: #0070C1"> <data-lsp lsp='const longerString: &amp;quot;alice&amp;quot; |
"bob"' >longerString</data-lsp></span><span style="color: #000000"> =
</span><span style="color: #795E26"><data-lsp lsp='function
longest<&amp;quot;alice&amp;quot; | &amp;quot;bob&amp;quot;>(a:
"alice" | "bob", b: "alice" |
"bob"): "alice" | "bob"
>longest</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"bob"</span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #008000">// Error! Numbers don't have a 'length'
```

property </div> < div class='line'> < span style="color: #0000FF"> const < span style="color: #000000"> < data-lsp lsp='const notOK: {
 length: number;
}' >notOK</data-lsp> = < data-lsp lsp='function longest&lt; {
 length: number;
}>(a: {
 length: number;
}, b: {
 length: number;
}): {
 length: number;
} >longest</data-lsp>(< data-err > 10 < /data-err > < span style="color: #000000">, < span style="color: #098658">100);</div> < span> Argument of type 'number' is not assignable to parameter of type '{ length: number; \\ '. < span class = "code" > 2345 < /span> < span class = "errorbehind">Argument of type 'number' is not assignable to parameter of type '{ length: number; }'. </code>Try</div>

There are few interesting things to note in this example. We allowed TypeScript to *infer* the return type of longest. Return type inference also works on generic functions.

Because we constrained Type to { length: number }, we were allowed to access the .length property of the a and b parameters. Without the type constraint, we wouldn't be able to access those properties because the values might have been some other type without a length property.

The types of longerArray and longerString were inferred based on the arguments. Remember, generics are all about relating two or more values with the same type!

Finally, just as we'd like, the call to longest (10, 100) is rejected because the number type doesn't have a .length property.

Working with Constrained Values

Here's a common error when working with generic constraints:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> minimumLength<Type extends {&#13; length: number;&#13;}>(obj: Type, minimum: number): Type' > minimumLength < /data-lsp > <<data-lsp lsp='(type parameter) Type in minimumLength<Type extends {&#13; length: number;&#13;}>(obj: Type, minimum: number): Type' >Type</data-lsp> extends { <span</pre> style="color: #001080"> < data-lsp lsp='(property) length: number' > length < /data-lsp > : number<span</pre>

```
style="color: #000000"> }>(</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='(parameter) obj: Type extends { length:
#267F99"> < data-lsp lsp='(type parameter) Type in minimumLength&amp;lt;Type extends
{
 length: number;
}>(obj: Type, minimum: number): Type' >Type</data-lsp>
</span><span style="color: #000000">,</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) minimum:
number' >minimum </data-lsp> </span> <span style="color: #000000">: </span> <span
style="color: #267F99">number</span></div><div class='line'><span style="color: #000000">):
</span><span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in
minimumLength<Type extends {&amp;#13; length: number;&amp;#13;}>(obj: Type,
minimum: number): Type' > Type</data-lsp> </span> < span style="color: #000000"> {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">if</span><span style="color: #000000"> (</span><span style="color: #001080">
<data-lsp lsp='(parameter) obj: Type extends { length: number; }' >obj</data-lsp></span><span</pre>
style="color: #000000">.</span><span style="color: #001080"><data-lsp lsp='(property) length:
number' >length</data-lsp></span><span style="color: #000000"> &gt;= </span><span
style="color: #001080"> < data-lsp lsp='(parameter) minimum: number' > minimum < /data-lsp>
</span><span style="color: #000000">) {</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #AF00DB">return</span><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) obj: Type extends {
length: number; }' >obj</data-lsp></span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> } </span><span style="color:
#AF00DB">else</span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #AF00DB">return</span><span
style="color: #000000"> { </span> < span style="color: #001080"> < data-lsp lsp='(property)
length: number' >length </data-lsp>:</span> <span style="color: #000000"> </span> <span
style="color: #001080"> < data-lsp lsp='(parameter) minimum: number' > minimum < /data-lsp>
</span><span style="color: #000000"> };</span></div><span class="error"><span>Type '{
length: number; }' is not assignable to type 'Type'. '{ length: number; }' is assignable to the
constraint of type 'Type', but 'Type' could be instantiated with a different subtype of constraint '{
length: number; \\.</span><span class="code">2322</span></span><span class="error-
behind">Type '{ length: number; }' is not assignable to type 'Type'. '{ length: number; }' is assignable
to the constraint of type 'Type', but 'Type' could be instantiated with a different subtype of
constraint '{ length: number; }'.</span><div class='line'><span style="color: #000000"> }</span>
</div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGY1oFADMBXAOwGMAX/
</div>
```

It might look like this function is OK - Type is constrained to { length: number }, and the function either returns Type or a value matching that constraint. The problem is that the function

promises to return the *same* kind of object as was passed in, not just *some* object matching the constraint. If this code were legal, you could write code that definitely wouldn't work:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000">//
'arr' gets value { length: 6 }</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const arr: number[]' >arr</data-lsp></span><span style="color: #000000"> =
</span><span style="color: #795E26"><data-lsp lsp='function
minimumLength<number[]>(obj: number[], minimum: number): number[]'
>minimumLength</data-lsp></span><span style="color: #000000">([</span><span
style="color: #098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">, </span><span style="color:
#098658">3</span><span style="color: #000000">], </span><span style="color:
#098658">6</span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #008000">// and crashes here because arrays have</span></div><div class='line'>
<span style="color: #008000">// a &apos;slice&apos; method, but not the returned object!
</span></div><div class='line'><span style="color: #001080"><data-lsp lsp='var console:
Console' >console</data-lsp></span><span style="color: #000000">.</span><span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='const arr: number[]' >arr </data-lsp> </span> < span style="color: #000000">.</span> < span
style="color: #795E26"> < data-lsp lsp='(method) Array&amp;lt;number>.slice(start?: number |
undefined, end?: number | undefined): number[]' >slice</data-lsp></span><span style="color:
#000000">(</span><span style="color: #098658">0</span><span style="color: #000000">));
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEAzArgOzAFwJYHtXwFstUsDkCAZEV
</div>
```

Specifying Type Arguments

TypeScript can usually infer the intended type arguments in a generic call, but not always. For example, let's say you wrote a function to combine two arrays:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </ span> < span style="color: #000000"> </ span> < span style="color: #795E26"> < data-lsp lsp='function combine&lt;Type> (arr1: Type[], arr2: Type[]): Type[]' > combine < / data-lsp lsp='function style="color: #000000"> & lt; </ span> < span style="color: #267F99"> < data-lsp lsp='function < span style="color: #000000"> & lt; </ span> < span style="color: #267F99"> < data-lsp lsp='function < span style="color: #267F99"> < data-lsp lsp='func

```
(arr1: Type[], arr2: Type[]): Type[]' > Type</data-lsp> </span> < span style="color: #000000">[],
</span><span style="color: #001080"><data-lsp lsp='(parameter) arr2: Type[]' >arr2</data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99"> < data-lsp
lsp='(type parameter) Type in combine<Type>(arr1: Type[], arr2: Type[]): Type[]'
>Type</data-lsp></span><span style="color: #000000">[]): </span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Type in combine&amp;lt;Type>(arr1: Type[], arr2:
Type[]): Type[]' >Type</data-lsp></span><span style="color: #000000">[] {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> <data-lsp lsp='(parameter) arr1: Type[]' > arr1 < /data-lsp > </span> < span style="color:
#000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Array<Type>.concat(...items: ConcatArray&amp;lt;Type>[]): Type[] (+1 overload)'
>concat</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> <data-lsp lsp='(parameter) arr2: Type[]' > arr2 < /data-lsp > </span> < span style="color:
#000000">);</span></div><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABBOBbARjMBTAPAFQE8AHbAPgA
</div>
```

Normally it would be an error to call this function with mismatched arrays:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> const </span> < <span style="color: #000000"> </span> <span style="color: #0070C1"> <data-lsp lsp='const arr: number[]' > arr </data-lsp > </span> <span style="color: #000000"> = </span> <span style="color: #795E26"> <data-lsp lsp='function combine&amp;lt;number> (arr1: number[], arr2: number[]): number[]' > combine </data-lsp> </span> <span style="color: #000000"> ([</span> <span style="color: #000000">, </span> <span style="color: #098658">1 </span> <span style="color: #000000">, </span> <span style="color: #098658">3 </span> <span style="color: #000000">, </span> <span style="color: #A31515"> <data-err> &quot;hello&quot; </data-err> </span> <span style="color: #000000">]); </span> <span class="error"> <span> Type 'string' is not assignable to type 'number'. </span> <span class="code">2322 </span> </span> </span> </span> <span class="error-behind"> Type 'string' is not assignable to type 'number'. </span> <span class="playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGY1oFABNIBjAGwENpJQA </div>
```

If you intended to do this, however, you could manually specify Type:

```
 < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const</span>
< span style="color: #000000"> </span> < span style="color: #0070C1"> < data-lsp lsp='const arr:
(string | number)[]' > arr < / data-lsp > < / span> < span style="color: #000000"> = < / span> < span
style="color: #795E26"> < data-lsp lsp='function combine& amp;lt;string | number> (arr1: (string | number)
```

```
number)[], arr2: (string | number)[]): (string | number)[]' >combine</data-lsp></span><span style="color: #000000">&lt;</span><span style="color: #267F99">string</span><span style="color: #000000"> | </span><span style="color: #267F99">number</span><span style="color: #000000"> &gt;([</span><span style="color: #098658">1</span><span style="color: #098658">1</span><span style="color: #000000">, </span><span style="color: #098658">2</span><span style="color: #000000">], </span><span style="color: #098658">3</span><span style="color: #000000">], [</span><span style="color: #000000">]);</span><</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEAzArgOzAFwJYHtXzBwFsAjLVEAHgl<</di></div>
```

Guidelines for Writing Good Generic Functions

Writing generic functions is fun, and it can be easy to get carried away with type parameters. Having too many type parameters or using constraints where they aren't needed can make inference less successful, frustrating callers of your function.

Push Type Parameters Down

Here are two ways of writing a function that appear similar:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
firstElement1<Type>(arr: Type[]): Type' > firstElement1 < /data-lsp> < /span> < span
style="color: #000000">&It;</span><span style="color: #267F99"><data-lsp lsp='(type
parameter) Type in firstElement1<Type>(arr: Type[]): Type' > Type</data-lsp> </span>
<span style="color: #000000">&qt;(</span><span style="color: #001080"><data-lsp</pre>
lsp='(parameter) arr: Type[]' >arr < /data-lsp> < /span> < span style="color: #000000">: < /span>
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in</pre>
firstElement1<Type>(arr: Type[]): Type' > Type</data-lsp> </span> < span style="color:
#000000">[]) {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #AF00DB">return</span><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(parameter) arr: Type[]' > arr < /data-lsp > </span> < span
style="color: #000000">[</span><span style="color: #098658">0</span><span style="color:
#000000">];</span></div><div class='line'><span style="color: #000000">}</span></div>
<div class='line'><span style="color: #0000FF">function</span><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='function firstElement2&amp;lt;Type extends
any[]>(arr: Type): any' >firstElement2</data-lsp></span><span style="color: #000000">&lt;
</span><span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in
firstElement2<Type extends any[]>(arr: Type): any' >Type</data-lsp></span><span
style="color: #000000"> </span><span style="color: #0000FF">extends</span><span
style="color: #000000"> </span><span style="color: #267F99">any</span><span style="color:
```

#000000">[]&qt;(<data-lsp lsp='(parameter) arr: Type extends any[]' >arr</data-lsp>: < data-lsp lsp='(type parameter) Type in firstElement2&lt;Type extends any[]>(arr: Type): any' >Type</data-lsp>) {</div><div class='line'> return < data-lsp lsp='(parameter) arr: Type extends any[]' > arr < /data-lsp > < /span > < span style="color: #000000">[0];</div><div class='line'>}</div> <div class='line'>// a: number (good)</div><div</pre> class='line'>const < data-lsp lsp='const a: number' > a < /data-lsp> < /span> < span</pre> style="color: #000000"> = < data-lsp lsp='function firstElement1<number>(arr: number[]): number' > firstElement1</data-lsp>([11, 2, 3]); </div><div class='line'>// b: any (bad)</div><div class='line'>const < data-lsp lsp='const b: any' > b < /data-lsp> < /span> < span</pre> style="color: #000000"> = < data-lsp lsp='function firstElement2<number[]>(arr: number[]): any' >firstElement2</data-lsp>([11, 2 , 3]); </div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABMGAnAzlAogGwKYC2eYUAjADw </div>

These might seem identical at first glance, but firstElement1 is a much better way to write this function. Its inferred return type is Type, but firstElement2 's inferred return type is any because TypeScript has to resolve the arr[0] expression using the constraint type, rather than "waiting" to resolve the element during a call.

Rule: When possible, use the type parameter itself rather than constraining it

Use Fewer Type Parameters

Here's another pair of similar functions:

 < div class='code-container' > < code > < div class='line' > < span style="color: #0000FF" > function < / span >

```
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
filter1<Type>(arr: Type[], func: (arg: Type) => boolean): Type[]' >filter1</data-lsp></span>
<span style="color: #000000">&lt;</span><span style="color: #267F99"><data-lsp lsp='(type</pre>
parameter) Type in filter1<Type>(arr: Type[], func: (arg: Type) => boolean): Type[]'
>Type</data-lsp></span><span style="color: #000000">&qt;(</span><span style="color:
#001080"> <data-lsp lsp='(parameter) arr: Type[]' > arr </data-lsp> </span> <span style="color:
#000000">: </span> <span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in
filter1<Type>(arr: Type[], func: (arg: Type) => boolean): Type[]' >Type</data-lsp></span>
<span style="color: #000000">[], </span><span style="color: #795E26"> <data-lsp</pre>
lsp='(parameter) func: (arg: Type) => boolean' >func</data-lsp></span><span style="color:</pre>
#000000">: (</span><span style="color: #001080"><data-lsp lsp='(parameter) arg: Type'
>arg</data-lsp></span><span style="color: #000000">: </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Type in filter1&amp;lt;Type>(arr: Type[], func: (arg: Type) =>
boolean): Type[]' > Type</data-lsp></span><span style="color: #000000">) </span><span
style="color: #0000FF">=&qt;</span><span style="color: #000000"> </span><span
style="color: #267F99">boolean</span><span style="color: #000000">): </span><span
style="color: #267F99"> < data-lsp lsp='(type parameter) Type in filter1&amp;lt;Type>(arr: Type[],
func: (arg: Type) => boolean): Type[]' > Type</data-lsp></span><span style="color: #000000">[]
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(parameter) arr: Type[]' > arr < /data-lsp > </span> < span style="color:
#000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Array<Type>.filter(predicate: (value: Type, index: number, array: Type[]) => unknown,
thisArg?: any): Type[] (+1 overload)' > filter </data-lsp> </span> < span style="color: #000000">
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) func: (arg: Type) => boolean'
>func</data-lsp></span><span style="color: #000000">);</span></div><div class='line'>
<span style="color: #000000">}</span></div> <div class='line'><span style="color:</pre>
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function filter2&amp;lt;Type, Func extends (arg: Type) => boolean>(arr:
Type[], func: Func): Type[]' > filter2 < /data-lsp > </span > < span style="color: #000000" > &lt; </span >
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in filter2&amp;lt;Type, Func</pre>
extends (arg: Type) => boolean>(arr: Type[], func: Func): Type[]' > Type</data-lsp></span><span
style="color: #000000">, </span><span style="color: #267F99"> < data-lsp lsp='(type parameter)
Func in filter2<Type, Func extends (arg: Type) => boolean>(arr: Type[], func: Func): Type[]'
>Func</data-lsp></span><span style="color: #000000"> </span><span style="color:
#0000FF">extends</span><span style="color: #000000"> (</span><span style="color:
#001080"> < data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in
filter2<Type, Func extends (arg: Type) => boolean>(arr: Type[], func: Func): Type[]'
>Type</data-lsp></span><span style="color: #000000">) </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color:
#267F99">boolean</span><span style="color: #000000">&qt;(</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp</pre>
```

lsp='(parameter) arr: Type[]' >arr < /data-lsp> < span style="color: #000000">: < data-lsp lsp='(type parameter) Type in filter2&lt;Type, Func</pre> extends (arg: Type) => boolean>(arr: Type[], func: Func): Type[]' > Type</data-lsp>[],</div><div class='line'> <data-lsp lsp='(parameter) func: Func extends (arg: Type) => boolean' >func</data-lsp>: < data-lsp lsp='(type parameter) Func in filter2&lt;Type, Func extends (arg: Type) => boolean>(arr: Type[], func: Func): Type[]' >Func</data-lsp></div><div class='line'>): <data-lsp lsp='(type parameter) Type in filter2<Type, Func extends (arg: Type) => boolean>(arr: Type[], func: Func): Type[]' >Type</data-lsp>[] { </div><div class='line'> return <data-lsp lsp='(parameter) arr: Type[]' > arr </data-lsp> .<data-lsp lsp='(method) Array<Type>.filter(predicate: (value: Type, index: number, array: Type[]) => unknown, thisArg?: any): Type[] (+1 overload)' > filter </data-lsp> < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) func: Func extends (arg: Type) => boolean' >func</data-lsp>);</div><div class='line'>}</div></code>Try</div>

We've created a type parameter Func that *doesn't relate two values*. That's always a red flag, because it means callers wanting to specify type arguments have to manually specify an extra type argument for no reason. Func doesn't do anything but make the function harder to read and reason about!

Rule: Always use as few type parameters as possible

Type Parameters Should Appear Twice

Sometimes we forget that a function might not need to be generic:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < span style="color: #000000"> < span style="color: #795E26"> < data-lsp lsp='function greet&lt;Str extends string> (s: Str): void' > greet < /data-lsp> < span style="color: #000000"> < < span style="color: #267F99"> < data-lsp lsp='(type parameter) Str in greet&lt;Str extends string> (s: Str): void' > Str < /data-lsp> < span style="color: #000000"> < span style="color: #0000FF"> extends < span style="color: #00000"> < span style="color: #267F99"> string < / span> < span style="color: #267F99"> string <

#000000">>(<data-lsp lsp='(parameter) s: Str extends string' >s</data-lsp>: < data-lsp lsp='(type parameter) Str in greet&lt;Str extends string>(s: Str): void' >Str</data-lsp>) {</div><div class='line'> <data-lsp lsp='var console: Console' > console < /data-lsp > < span style = "color: #000000" > . < /span > < span style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> ("Hello, " + <data-lsp</pre> lsp='(parameter) s: Str extends string' >s</data-lsp>); </div><div class='line'>}</div> <div class='line'><data-lsp lsp='function greet<&quot;world&quot;>(s: &quot;world&quot;): void' > greet < /datalsp>("world");</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAcwE4FN1QDwGUgqLoAeU6YAJ </div>

We could just as easily have written a simpler version:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> greet(s: string): void' > greet < /data-lsp > < span style="color: #000000" > (< span style="color: #001080"> < data-lsp lsp='(parameter) s: string' > s < /data-lsp > < /span> < span style="color: #000000">: string) {</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp> .<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>("Hello, " + < data-lsp lsp='(parameter) s: string' >s</data-lsp>);</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAcwE4FN1QBQGcBciuUqMYyAlle </div>

Remember, type parameters are for *relating the types of multiple values*. If a type parameter is only used once in the function signature, it's not relating anything.

Rule: If a type parameter only appears in one location, strongly reconsider if you actually need it

Optional Parameters

Functions in JavaScript often take a variable number of arguments. For example, the toFixed method of number takes an optional digit count:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
f(n: number): void' >f</data-lsp></span><span style="color: #000000">(</span><span
style="color: #001080"> < data-lsp lsp='(parameter) n: number' > n < /data-lsp > </span> < span
style="color: #000000">: </span><span style="color: #267F99">number</span><span
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"> <data-lsp lsp='(parameter) n: number'
>n</data-lsp></span><span style="color: #000000">.</span><span style="color: #795E26">
<data-lsp lsp='(method) Number.toFixed(fractionDigits?: number | undefined): string'</pre>
>toFixed</data-lsp></span><span style="color: #000000">()); </span><span style="color:
#008000">// 0 arguments </span> </div> <div class='line'> <span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"> <data-lsp lsp='(parameter) n: number'
>n</data-lsp></span><span style="color: #000000">.</span><span style="color: #795E26">
<data-lsp lsp='(method) Number.toFixed(fractionDigits?: number | undefined): string'</p>
>toFixed</data-lsp></span><span style="color: #000000">(</span><span style="color:
#098658">3</span><span style="color: #000000">)); </span><span style="color: #008000">//
1 argument</span></div><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABMAFGAXIsIC2AjAUwCcBKRAbwC
</div>
```

We can model this in TypeScript by marking the parameter as *optional* with ?:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </span> < span style="color: #000000"> </span> < span style="color: #795E26"> < data-lsp lsp='function f(x?: number | undefined): void' > f < / data-lsp> < / span> < span style="color: #000000"> (< / span> < span style="color: #001080"> < data-lsp lsp='(parameter) x: number | undefined' > x < / data-lsp> </span> < span style="color: #000000"> ?: </span> < span style="color: #267F99"> number < / span> < span style="color: #000000"> (< / span> < / div> < div class='line'> < span style="color: #000000"> // ... < / span> < / div> < div</pre>
```

```
class='line'> <span style="color: #000000">} </span> </div> <div class='line'> <span style="color: #795E26"> <data-lsp lsp='function f(x?: number | undefined): void' >f </data-lsp> </span> <span style="color: #000000">(); </span> <span style="color: #008000">// OK </span> </div> <div class='line'> <span style="color: #795E26"> <data-lsp lsp='function f(x?: number | undefined): void' >f </data-lsp> </span> <span style="color: #000000">(</span> <span style="color: #008000">// OK </span> <span style="color: #008000">// OK </span> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABMAFADwPwC5FhAWwCMBTAJw </div>
```

Although the parameter is specified as type number, the x parameter will actually have the type number | undefined because unspecified parameters in JavaScript get the value undefined.

You can also provide a parameter default.

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #00000FF"> function </span> <span style="color: #000000"> </span> <span style="color: #795E26"> <data-lsp lsp='function f(x?: number): void' >f </data-lsp </span> <span style="color: #000000"> (</span> <span style="color: #001080"> <data-lsp lsp='(parameter) x: number' > x </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #098658"> 10 </span> <span style="color: #000000"> (</span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> </div> <div class='line'> <span style="color: #000000"> (</span> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABMAFAD0QXkQRgAwCUiA3gFCKI </div>
```

Now in the body of f, x will have type number because any undefined argument will be replaced with 10. Note that when a parameter is optional, callers can always pass undefined, as this simply simulates a "missing" argument:

<div class='code-container'> <code> <div class='line'> declare function <data-lsp lsp='function f(x?: number | undefined): void' >f </data-lsp> (((number (number number (div (div (div </span)

```

```

Optional Parameters in Callbacks

Once you've learned about optional parameters and function type expressions, it's very easy to make the following mistakes when writing functions that invoke callbacks:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
myForEach(arr: any[], callback: (arg: any, index?: number | undefined) => void): void'
>myForEach</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> <data-lsp lsp='(parameter) arr: any[]' >arr </data-lsp> </span> <span style="color:
#000000">: </span> <span style="color: #267F99">any </span> <span style="color: #000000">[],
</span><span style="color: #795E26"><data-lsp lsp='(parameter) callback: (arg: any, index?:
number | undefined) => void' >callback</data-lsp></span><span style="color: #000000">:
(</span> <span style="color: #001080"> <data-lsp lsp='(parameter) arg: any' >arg </data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">any</span>
<span style="color: #000000">, </span><span style="color: #001080"> <data-lsp</pre>
lsp='(parameter) index: number | undefined' >index</data-lsp></span><span style="color:
#000000">?: </span> <span style="color: #267F99">number </span style="color: #267F999">number </span style="color: #267F999">number </span style="color: #267F999">number </span style="color: #267F9999</span style="color: #267F9999</span style="color: #267F9999</span st
#000000">) </span> <span style="color: #0000FF"> = &qt; </span> <span style="color: #000000">
</span><span style="color: #267F99">void</span><span style="color: #000000">) {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">for</span><span style="color: #000000"> (</span><span style="color:
#0000FF">let</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='let i: number' >i</data-lsp></span><span style="color: #000000"> = </span>
<span style="color: #098658">0</span><span style="color: #000000">; </span><span</pre>
style="color: #001080" > <data-lsp lsp='let i: number' > i </data-lsp> </span> <span style="color:
#000000"> < </span><span style="color: #001080"> <data-lsp lsp='(parameter) arr: any[]'
>arr</data-lsp></span><span style="color: #000000">.</span><span style="color: #001080">
<data-lsp lsp='(property) Array&amp;lt;any>.length: number' >length</data-lsp></span><span
style="color: #000000">; </span><span style="color: #001080"> < data-lsp lsp='let i: number'
>i</data-lsp></span><span style="color: #000000">++) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp</pre>
lsp='(parameter) callback: (arg: any, index?: number | undefined) => void' >callback</data-lsp>
```

What people usually intend when writing index? as an optional parameter is that they want both of these calls to be legal:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #795E26"> < data-lsp
lsp='function myForEach(arr: any[], callback: (arg: any, index?: number | undefined) => void): void'
>myForEach</data-lsp></span><span style="color: #000000">([</span><span style="color:
#098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">, </span><span style="color:
#098658">3</span><span style="color: #000000">], (</span><span style="color: #001080">
<data-lsp lsp='(parameter) a: any' >a</data-lsp></span><span style="color: #000000">)
</span><span style="color: #0000FF">=&gt;</span><span style="color: #000000"> </span>
<span style="color: #001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span>
<span style="color: #000000">.</span><span style="color: #795E26"> < data-lsp lsp='(method)</pre>
Console.log(...data: any[]): void' >log</data-lsp></span><span style="color: #000000">(</span>
<span style="color: #001080"> < data-lsp lsp='(parameter) a: any' > a < /data-lsp> < /span> < span</pre>
style="color: #000000">));</span></div><div class='line'><span style="color: #795E26"><data-
lsp lsp='function myForEach(arr: any[], callback: (arg: any, index?: number | undefined) => void):
void' >myForEach</data-lsp></span><span style="color: #000000">([</span><span
style="color: #098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">, </span><span style="color:
#098658">3</span><span style="color: #000000">], (</span><span style="color: #001080">
<data-lsp lsp='(parameter) a: any' >a</data-lsp></span><span style="color: #000000">,
</span><span style="color: #001080"><data-lsp lsp='(parameter) i: number | undefined'
>i</data-lsp></span><span style="color: #000000">) </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='var console: Console' >console</data-lsp></span><span style="color: #000000">.
</span><span style="color: #795E26"><data-lsp lsp='(method) Console.log(...data: any[]): void'
>log</data-lsp></span><span style="color: #000000">(</span><span style="color: #001080">
<data-lsp lsp='(parameter) a: any' >a</data-lsp></span><span style="color: #000000">,
</span><span style="color: #001080"><data-lsp lsp='(parameter) i: number | undefined'
>i</data-lsp></span><span style="color: #000000">));</span></div></code><a
class='playground-link'
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMaBQATSAYwBsBDaSU</div>

What this *actually* means is that *callback might get invoked with one argument*. In other words, the function definition says that the implementation might look like this:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
myForEach(arr: any[], callback: (arg: any, index?: number | undefined) => void): void'
>myForEach</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> <data-lsp lsp='(parameter) arr: any[]' >arr </data-lsp> </span> <span style="color:
#000000">: </span> <span style="color: #267F99">any </span> <span style="color: #000000">[],
</span><span style="color: #795E26"><data-lsp lsp='(parameter) callback: (arg: any, index?:
number | undefined) => void' >callback</data-lsp></span><span style="color: #000000">:
(</span> <span style="color: #001080"> <data-lsp lsp='(parameter) arg: any' > arg </data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">any</span>
<span style="color: #000000">, </span><span style="color: #001080"> <data-lsp</pre>
lsp='(parameter) index: number | undefined' >index</data-lsp></span><span style="color:
#000000">?: </span> <span style="color: #267F99">number </span style="color: #267F999">number </span style="color: #267F9999">number </span style="color: #267F9999">number </span style="color: #267F99999</span style="color: #267F99999</span style="color: #267F99999</span style="color: #267F99
#000000">) </span> <span style="color: #0000FF"> = &qt; </span> <span style="color: #000000">
</span><span style="color: #267F99">void</span><span style="color: #000000">) {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">for</span><span style="color: #000000"> (</span><span style="color:
#0000FF">let</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='let i: number' >i</data-lsp></span><span style="color: #000000"> = </span>
<span style="color: #098658">0</span><span style="color: #000000">; </span><span</pre>
style="color: #001080"> <data-lsp lsp='let i: number' >i </data-lsp> </span> <span style="color:
#000000"> < </span><span style="color: #001080"> <data-lsp lsp='(parameter) arr: any[]'
>arr</data-lsp></span><span style="color: #000000">.</span><span style="color: #001080">
<data-lsp lsp='(property) Array&amp;lt;any>.length: number' >length</data-lsp></span><span
style="color: #000000">; </span> <span style="color: #001080"> <data-lsp lsp='let i: number'
>i</data-lsp></span><span style="color: #000000">++) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #008000">// I don&apos;t feel like
providing the index today </span> </div> < div class='line'> < span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='(parameter) callback: (arg: any, index?:
number | undefined) => void' >callback</data-lsp> </span> <span style="color: #000000">
(</span> <span style="color: #001080"> <data-lsp lsp='(parameter) arr: any[]' >arr </data-lsp>
</span><span style="color: #000000">[</span><span style="color: #001080"><data-lsp lsp='let
i: number' >i</data-lsp></span><span style="color: #000000">]);</span></div><div
class='line'><span style="color: #000000"> }</span></div><div class='line'><span style="color:
#000000">}</span></div></code><a class='playground-link'
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMaBQAzAVwDsBjAFw </div>

In turn, TypeScript will enforce this meaning and issue errors that aren't really possible:

<!-- prettier-ignore --> class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div class='code-container'> < code> < div class='line'> < span style="color: #795E26"> < data-lsp lsp='function myForEach(arr: any[], callback: (arg: any, index?: number | undefined) => void): void' >myForEach</data-lsp>([1, 2, 3], (], (], (], (], (], (</span style="color: #000000")], (</span style="color: #0000000")], (<data-lsp lsp='(parameter) a: any' >a </data-lsp> , <data-lsp lsp='(parameter) i: number | undefined' >i</data-lsp>) =><span style="color: <math>\#000000"> \{</div><div class='line'><span style="color: <math>\#000000"> \{</div></div></div></div></div></div></div>$ style="color: #000000"> <data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-err> <data-lsp lsp='(parameter) i: number | undefined' >i</data-lsp></data-err>.<data-lsp lsp='(method) Number.toFixed(fractionDigits?: number | undefined): string' >toFixed</data-lsp>());</div>Object is possibly 'undefined'.2532Object is possibly 'undefined'.<div class='line'>}); </div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMaBQATSAYwBsBDaSU </div>

In JavaScript, if you call a function with more arguments than there are parameters, the extra arguments are simply ignored. TypeScript behaves the same way. Functions with fewer parameters (of the same types) can always take the place of functions with more parameters.

When writing a function type for a callback, *never* write an optional parameter unless you intend to *call* the function without passing that argument

Function Overloads

Some JavaScript functions can be called in a variety of argument counts and types. For example, you might write a function to produce a Date that takes either a timestamp (one argument) or a month/day/year specification (three arguments).

In TypeScript, we can specify a function that can be called in different ways by writing *overload signatures*. To do this, write some number of function signatures (usually two or more), followed by the body of the function:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
makeDate(timestamp: number): Date (+1 overload)' > makeDate</data-lsp></span><span
style="color: #000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter)
timestamp: number' >timestamp</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99">number</span><span style="color: #000000">): </span><span</pre>
style="color: #267F99"> < data-lsp lsp='interface Date' > Date < /data-lsp > </span> < span
style="color: #000000">;</span></div><div class='line'><span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function makeDate(m: number, d: number, y: number): Date (+1
overload)' >makeDate</data-lsp></span><span style="color: #000000">(</span><span
style="color: #001080"> < data-lsp lsp='(parameter) m: number' > m < /data-lsp > </span> < span
style="color: #000000">: </span><span style="color: #267F99">number</span><span
style="color: #000000">, </span><span style="color: #001080"> <data-lsp lsp='(parameter) d:
number' >d</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000">, </span><span style="color:
#001080"> < data-lsp lsp='(parameter) y: number' > y < /data-lsp > </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F9999"> number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999</span style="c
#000000">): </span><span style="color: #267F99"> <data-lsp lsp='interface Date' > Date </data-
lsp></span><span style="color: #000000">;</span></div><div class='line'><span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function makeDate(timestamp: number): Date (+1 overload)'
>makeDate</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) mOrTimestamp: number' > mOrTimestamp < /data-lsp>

= </span><span style="color: #795E26"> < data-lsp lsp='function makeDate(timestamp: number):
Date (+1 overload)' > makeDate < /data-lsp > </span > < span style="color: #000000" > (</span >
<span style="color: #098658">1</span><span style="color: #000000">, </span><span</pre>
style="color: #098658">3</span><span style="color: #000000">);</span></div><span
class="error"> < span> No overload expects 2 arguments, but overloads do exist that expect either 1
```

or 3 arguments.2575No overload expects 2 arguments, but overloads do exist that expect either 1 or 3 arguments.</code>Try</div>

In this example, we wrote two overloads: one accepting one argument, and another accepting three arguments. These first two signatures are called the *overload signatures*.

Then, we wrote a function implementation with a compatible signature. Functions have an *implementation* signature, but this signature can't be called directly. Even though we wrote a function with two optional parameters after the required one, it can't be called with two parameters!

Overload Signatures and the Implementation Signature

This is a common source of confusion. Often people will write code like this and not understand why there is an error:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
fn(x: string): void' >fn</data-lsp></span><span style="color: #000000">(</span><span
style="color: #001080"> < data-lsp lsp='(parameter) x: string' > x < /data-lsp > </span> < span

```

Again, the signature used to write the function body can't be "seen" from the outside.

</div>

The signature of the *implementation* is not visible from the outside. When writing an overloaded function, you should always have *two* or more signatures above the implementation of the function.

The implementation signature must also be *compatible* with the overload signatures. For example, these functions have errors because the implementation signature doesn't match the overloads in a correct way:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>

</div>
```

Writing Good Overloads

Like generics, there are a few guidelines you should follow when using function overloads. Following these principles will make your function easier to call, easier to understand, and easier to implement.

Let's consider a function that returns the length of a string or an array:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> function </span> <span style="color: #000000"> </span> <span style="color: #795E26"> <data-lsp lsp='function len(s: string): number (+1 overload)' >len </data-lsp > </span> <span style="color: #000000"> (</span> <span style="color: #001080"> <data-lsp lsp='(parameter) s: string' >s </data-lsp> </span> <span style="color: #000000">: </span> <span style="color: #267F99"> string </span> <span style="color: #267F99"> number </span> <span style="color: #267F99"> numbe
```

```
style="color: #267F99">number </span> <span style="color: #00000">;</span> </div> <div class='line'> <span style="color: #0000FF">function </span> <span style="color: #000000"> </span> <span style="color: #795E26"> <data-lsp lsp='function len(s: string): number (+1 overload)' >len </data-lsp > </span> <span style="color: #000000"> (</span> <span style="color: #001080"> <data-lsp lsp='(parameter) x: any' >x</data-lsp> </span> <span style="color: #000000"> (</span> </span> </span style="color: #000000"> (</span> </span> <
```

This function is fine; we can invoke it with strings or arrays. However, we can't invoke it with a value that might be a string *or* an array, because TypeScript can only resolve a function call to a single overload:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #795E26"> < data-lsp lsp='function len(s: string): number (+1 overload)' >len</data-lsp>(""); // OK</div><div class='line'> < data-lsp lsp='function len(arr: any[]): number (+1 overload)' > len < /data-lsp > < /span> ([0<span</pre> style="color: #000000">]); // OK</div><div class='line'><data-lsp lsp='function len(s: string): number (+1 overload)' >len < /data-lsp > ((< #267F99"> < data-lsp lsp='var Math: Math' > Math < /data-lsp> < span style="color: #000000">.<data-lsp lsp='(method) Math.random(): number' >random</data-lsp>() > 0.5? "hello" < span style = "color: #000000"> : [< span style = "color: #000000"> #098658">0]);</div> No overload matches this call. Overload 1 of 2, '(s: string): number', gave the following error. Argument of type 'number[] | "hello" is not assignable to parameter of type 'string'. Type 'number[]' is not assignable to type 'string'. Overload 2 of 2, '(arr: any[]): number', gave the following error. Argument of type 'number[] | "hello" is not assignable to parameter of type 'any[]'. Type 'string' is not assignable to type 'any[]'.2769 No overload matches this call. Overload 1 of 2, '(s: string): number', gave the following error. Argument of type 'number[] | "hello" is not assignable to parameter of type 'string'. Type 'number[]' is not assignable to type 'string'. Overload 2 of 2, '(arr: any[]): number', gave the following error. Argument of type 'number[] | "hello" is not assignable to

parameter of type 'any[]'. Type 'string' is not assignable to type 'any[]'.</code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwHYBsBOAUACaQDGANgIk </div>

Because both overloads have the same argument count and same return type, we can instead write a non-overloaded version of the function:

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function len(x: any[] | string): number' > len </data-lsp (<data-lsp lsp='(parameter) x: string | any[]' >x </data-lsp> : any [] | string (</div> <div class='line'> <data-lsp lsp='(parameter) x: string | any[]' >x </data-lsp <data-lsp lsp='(parameter) x: string | any[]' >x </data-lsp <data-lsp lsp='(property) length: number' >length </data-lsp> </div> <div <lass='line'> </div> </div> </dote> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAGwKZgBQA8BciCGYAngNoC6iA </div>

This is much better! Callers can invoke this with either sort of value, and as an added bonus, we don't have to figure out a correct implementation signature.

Always prefer parameters with union types instead of overloads when possible

Declaring this in a Function

TypeScript will infer what the this should be in a function via code flow analysis, for example in the following:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> < const < span style="color: #000000"> < span style="color: #0070C1"> < data-lsp lsp='const user: {&#13; id: number;&#13; admin: boolean;&#13; becomeAdmin: () => void;&#13;}' > user < /data-lsp> < /span> < span style="color: #000000"> = { < /span> < /div> < div class='line'> < span style="color: #001080"> < data-lsp lsp='(property) id: number' > id < /data-lsp>: < /span> < span style="color: #000000"> < /span> < span style="color: #000000"> < /span> < /span> < /div> < div class='line'> < span style="color: #000000"> < /span> < span style="color: #000000"> < /span> < /s

lsp='(property) admin: boolean' >admin</data-lsp>: false , </div> <div class='line'> <data-lsp lsp='(property) becomeAdmin: () => void' >becomeAdmin</data-lsp> : this <span style

TypeScript understands that the function user.becomeAdmin has a corresponding this which is the outer object user. this, heh, can be enough for a lot of cases, but there are a lot of cases where you need more control over what object this represents. The JavaScript specification states that you cannot have a parameter called this, and so TypeScript uses that syntax space to let you declare the type for this in the function body.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> DB' >DB < /data-lsp > { </div > <div class='line' > <data-lsp lsp='(method)</pre> DB.filterUsers(filter: (this: User) => boolean): User[]' >filterUsers</data-lsp>(<data-lsp lsp='(parameter) filter: (this: User) => boolean' >filter</data-lsp>: (< data-lsp lsp='(parameter) this: User' > this < /data-lsp> < /span> : <data-lsp lsp='interface</pre> User' >User</data-lsp>) => boolean): < data-lsp lsp='interface User' > User < /data-lsp> < /span> < span style="color: #000000">[];</div><div class='line'>}</div> <div class='line'>const <data-lsp lsp='const db: DB' >db</data-lsp> = <data-lsp lsp='const</pre> getDB: () => DB' >getDB</data-lsp>();</div> <div class='line'>const <data-lsp lsp='const admins: User[]' >admins</data-lsp> = < data-lsp

This pattern is common with callback-style APIs, where another object typically controls when your function is called. Note that you need to use function and not arrow functions to get this behavior:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> DB' > DB < /data-lsp > { </div > <div class='line' > <data-lsp lsp='(method)</pre> DB.filterUsers(filter: (this: User) => boolean): User[]' >filterUsers</data-lsp>(<data-lsp lsp='(parameter) filter: (this: User) => boolean' >filter</data-lsp>: (< data-lsp lsp='(parameter) this: User' > this < /data-lsp> < /span> : <data-lsp lsp='interface</pre> User' >User</data-lsp>) => boolean): < data-lsp lsp='interface User' > User < /data-lsp> < /span> < span style="color: #000000">[];</div><div class='line'>}</div> <div class='line'>const <data-lsp lsp='const db: DB' >db</data-lsp> = <data-lsp lsp='const</pre> getDB: () => DB' >getDB</data-lsp>();</div> <div class='line'>const <data-lsp lsp='const admins: User[]' >admins</data-lsp> = < data-lsp lsp='const db: DB' >db</data-lsp>. < data-lsp lsp='(method) DB.filterUsers(filter: (this: User) => boolean):

User[]' > filterUsers </data-lsp > (() () = > . . <data-err> </data-lsp | sp='any' > admin </data-lsp> </data-err>); </div> < The containing arrow function captures the global value of 'this'. </br> Element implicitly has an 'any' type because type 'typeof globalThis' has no index signature. 7041
 br/> 7017 The containing arrow function captures the global value of 'this'. </br> Element implicitly has an 'any' type because type 'typeof globalThis' has no index signature. </code> Try </div>

Other Types to Know About

There are some additional types you'll want to recognize that appear often when working with function types. Like all types, you can use them everywhere, but these are especially relevant in the context of functions.

void

void represents the return value of functions which don't return a value. It's the inferred type any time a function doesn't have any return statements, or doesn't return any explicit value from those return statements:

<div
class='code-container'> <code> <div class='line'> // The inferred
return type is void </div> <div class='line'> <span style="color:
#0000FF"> function <span style="color:
#795E26"> <data-lsp lsp='function noop(): void' >noop </data-lsp> <span style="color:
#000000">() { </div> <div class='line'> </div> <div
style="color: #AF00DB"> return ; </div> <div
class='line'> </div> <div
class='line'> </div> <div
class='line'> </div> </div

In JavaScript, a function that doesn't return any value will implicitly return the value undefined. However, void and undefined are not the same thing in TypeScript. There are further details at the end of this chapter.

void is not the same as undefined.

object

The special type object refers to any value that isn't a primitive (string, number, boolean, symbol, null, or undefined). This is different from the *empty object type* { }, and also different from the global type Object. It's very likely you will never use Object.

```
object is not Object . Always use object!
```

Note that in JavaScript, function values are objects: They have properties, have Object.prototype in their prototype chain, are instanceof Object, you can call Object.keys on them, and so on. For this reason, function types are considered to be object s in TypeScript.

unknown

The unknown type represents *any* value. This is similar to the any type, but is safer because it's not legal to do anything with an unknown value:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF" > function < / span> <data-lsp lsp='function</pre> f1(a: any): void' >f1 </data-lsp> (< data-lsp lsp='(parameter) a: any' >a < /data-lsp> < /span> < span style="color: #000000">: any) {</div><div class='line'> < data-lsp lsp='(parameter) a: any' >a < /data-lsp> < /span> < span style="color: #000000">.<data-lsp lsp='any' >b</datalsp>(); // OK</div><div class='line'>}</div><div class='line'>function <data-lsp lsp='function f2(a: unknown): void' >f2</datalsp>(<data-lsp lsp='(parameter) a: unknown' >a</data-lsp>: unknown) {</div> <div class='line'> <data-</pre> err> < data-lsp lsp='(parameter) a: unknown' >a < /data-lsp> < /data-err> < /span> < span style="color: #000000">.<data-lsp lsp='any' >b</datalsp>();</div>Object is of type 'unknown'.2571Object is of type 'unknown'.<div class='line'>} </div></code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDsBGAUAGYCuAdgMYA</div>

This is useful when describing function types because you can describe functions that accept any value without having any values in your function body.

Conversely, you can describe a function that returns a value of unknown type:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> safeParse(s: string): unknown' >safeParse</data-lsp> (< span style="color: #001080"> < data-lsp lsp='(parameter) s: string' > s < /data-lsp> : string): unknown<span</pre> style="color: #000000"> {</div><div class='line'> return <data-lsp lsp='var JSON: JSON' >JSON </data-lsp> <span</pre> style="color: #000000">.<data-lsp lsp='(method) JSON.parse(text: string, reviver?: ((this: any, key: string, value: any) => any) | undefined): any' >parse</data-lsp>(< data-lsp lsp='(parameter) s: string' > s < /data-lsp > < /span > < span style="color: #000000">);</div><div class='line'>}</div> <div class='line'>// Need to be careful with 'obj'! </div><div class='line'>const <data-lsp lsp='const obj: unknown' >obj</data-lsp> = <data-lsp lsp='function safeParse(s: string): unknown' >safeParse </data-lsp> (<data-lsp lsp='const</pre> someRandomString: string' > someRandomString < /data-lsp > < span style="color: #000000">);</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEYD2A7AzgF3mpBbEASICsHgMoYw(YAK4Z+vdgDNBKMBiqpsUcSAAKsNCAAUaRpmp0AllykBrFEgDuKeAG928eHAyCYVgFJkA8gDkAdAAc1TT </div>

never

Some functions *never* return a value:

```
style="color: #000000">: </span> <span style="color: #267F99">string</span> <span style="color: #000000">: </span> <span style="color: #267F99">never</span> <span style="color: #000000"> (</span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #00000FF">new</span> <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='var Error: ErrorConstructor&amp;#13;new (message?: string | undefined) => Error' >Error</data-lsp> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) msg: string' >msg</data-lsp> </span> <span style="color: #000000">);</span> </div> <div class='line'> <span style="color: #000000">} </span> </div> </div>
```

The never type represents values which are *never* observed. In a return type, this means that the function throws an exception or terminates execution of the program.

never also appears when TypeScript determines there's nothing left in a union.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
fn(x: string | number): void' >fn</data-lsp></span><span style="color: #000000">(</span>
<span style="color: #001080"> < data-lsp lsp='(parameter) x: string | number' > x < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">string</span>
<span style="color: #000000"> | </span><span style="color: #267F99">number</span><span</pre>
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #AF00DB">if</span><span style="color: #000000"> (</span><span

```

Function

The global type Function describes properties like bind, call, apply, and others present on all function values in JavaScript. It also has the special property that values of type Function can always be called; these calls return any:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> < span style="color: #000000"> < / span> < span style="color: #795E26"> < data-lsp lsp='function < doSomething(f: Function): void'> doSomething < / data-lsp> < / span> < span style="color: #795E26"> < data-lsp lsp='(parameter) f: Function' </pre>
#000000"> (</ span> < span style="color: #795E26"> < data-lsp lsp='(parameter) f: Function' </pre>
\$ < data-lsp lsp='interface Function'> Function < / data-lsp> < / span> < span style="color: #000000"> (</ span> < / div> < div class='line'> < span style="color: #000000"> < / span> < span style="color: #000000"> (</ span

This is an *untyped function call* and is generally best avoided because of the unsafe any return type.

If you need to accept an arbitrary function but don't intend to call it, the type () => void is generally safer.

Rest Parameters and Arguments

<blockquote class='bg-reading'> Background Reading:
 Rest Parameters
 Spread Syntax

</blockquote>

Rest Parameters

In addition to using optional parameters or overloads to make functions that can accept a variety of fixed argument counts, we can also define functions that take an *unbounded* number of arguments using *rest parameters*.

A rest parameter appears after all other parameters, and uses the ... syntax:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
multiply(n: number, ...m: number[]): number[]' > multiply < /data-lsp > </span > <span style="color:
#000000">(</span><span style="color: #001080"> <data-lsp lsp='(parameter) n: number'
>n</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000">, ...</span><span style="color:
#001080"> < data-lsp lsp='(parameter) m: number[]' > m < /data-lsp > </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F9999"> number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999</span style="c
#000000">[]) {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #AF00DB">return</span><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(parameter) m: number[]' > m < /data-lsp > </span> < span
style="color: #000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Array<number>.map&amp;lt;number>(callbackfn: (value: number, index: number, array:
number[]) => number, thisArg?: any): number[]' >map</data-lsp></span><span style="color:
#000000">((</span><span style="color: #001080"> <data-lsp lsp='(parameter) x: number'
>x</data-lsp></span><span style="color: #000000">) </span><span style="color:
#0000FF">=&qt;</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(parameter) n: number' >n</data-lsp></span><span style="color: #000000"> *
</span><span style="color: #001080"><data-lsp lsp='(parameter) x: number' >x</data-lsp>
</span><span style="color: #000000">);</span></div><div class='line'><span style="color:
#000000">}</span></div><div class='line'><span style="color: #008000">// &apos;a&apos;
gets value [10, 20, 30, 40] </span> </div> < div class='line'> < span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const a: number[]' >a</data-lsp></span><span style="color: #000000"> =
</span><span style="color: #795E26"><data-lsp lsp='function multiply(n: number, ...m: number[]):
number[]' >multiply </data-lsp> </span> <span style="color: #000000">(</span> <span
style="color: #098658">10</span><span style="color: #000000">, </span><span style="color:
#098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">, </span><span style="color:
#098658">3</span><span style="color: #000000">, </span><span style="color:
#098658">4</span><span style="color: #000000">);</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAWxAG1gBzQTwBRgBciYlyARgK'
</div>
```

In TypeScript, the type annotation on these parameters is implicitly any[] instead of any, and any type annotation given must be of the form Array<T> or T[], or a tuple type (which we'll learn about later).

Rest Arguments

Conversely, we can *provide* a variable number of arguments from an array using the spread syntax. For example, the push method of arrays takes any number of arguments:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const</span>
<span style="color: #000000"> </span><span style="color: #0070C1"> < data-lsp lsp='const arr1:</pre>
number[]' >arr1 < /data-lsp > </span > <span style="color: #000000" > = [ </span > <span
style="color: #098658">1</span><span style="color: #000000">, </span><span style="color:
#098658">2</span><span style="color: #000000">, </span><span style="color:
#098658">3</span><span style="color: #000000">];</span></div><div class='line'><span
style="color: #0000FF">const</span><span style="color: #000000"> </span><span style="color:
#0070C1"> < data-lsp lsp='const arr2: number[]' > arr2 < /data-lsp> < /span> < span style="color:
\#000000" = [</span> < span style="color: \#098658" > 4 </span> < span style="color: \#000000" >,
</span><span style="color: #098658">5</span><span style="color: #000000">, </span><span
style="color: #098658">6</span><span style="color: #000000">];</span></div><div
class='line'><span style="color: #001080"><data-lsp lsp='const arr1: number[]' >arr1</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Array<number>.push(...items: number[]): number' >push</data-lsp>
</span> < span style="color: #000000"> (... < /span> < span style="color: #001080"> < data-lsp
lsp='const arr2: number[]' >arr2</data-lsp></span><span style="color: #000000">);</span>
</div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/\#code/MYewdgzgLgBAhgJwQRhgXhgbWQGhgJjwGYBdAbgCallered for the control of the contr
</div>
```

Note that in general, TypeScript does not assume that arrays are immutable. This can lead to some surprising behavior:

< div class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Inferred type is number[] -- "an array with zero or more numbers", < /div> < div class='line'> < span style="color: #008000"> // not specifically two numbers < /div> < div class='line'> < span style="color: #00000FF"> const < span style="color: #000000"> < span style="color: #0070C1"> < data-lsp lsp='const args: number[]' > args </data-lsp> < span style="color: #000000"> , < span style="color: #098658"> 8 < span style="color: #000000">]; < /div> < div class='line'> < span style="color: #000000"> < < span s

 = <data-lsp
lsp='var Math: Math' > Math </data-lsp> .. <data-lsp lsp='(method) Math.atan2(y: number, x: number): number'
> atan2 </data-lsp> (... <span style="color:
#001080"> <data-lsp lsp='const args: number[]' > args </data-lsp> <span style="color:
#000000">); </div> Expected 2 arguments, but got 0 or
more. Expected 2
arguments, but got 0 or more. </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYMDYBQJQBJAOwDMZp
</div>

The best fix for this situation depends a bit on your code, but in general a const context is the most straightforward solution:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Inferred as 2length tuple</div><div class='line'>const < data-lsp lsp='const args: readonly [8, 5]' >args</data-lsp> = [8, 5] as <data-lsp lsp='any' >const</data-lsp>;</div> <div class='line'>// OK</div><div class='line'><span</pre> style="color: #0000FF">const < data-lsp lsp='const angle: number' > angle < /data-lsp > < span style="color: #000000"> = < data-lsp lsp='var Math: Math' >Math</data-lsp>. < data-lsp lsp='(method) Math.atan2(y: number, x: number): number' > atan2 < /datalsp>(...<data-lsp lsp='const args: readonly [8, 5]' >args</data-lsp>); </div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEEkDsDMFMCd6wCagIYGdQCYC0AbWSAcwBcALl </div>

Using rest arguments may require turning on <u>downlevelIteration</u> when targeting older runtimes.

<!-- TODO link to downlevel iteration -->

Parameter Destructuring

You can use parameter destructuring to conveniently unpack objects provided as an argument into one or more local variables in the function body. In JavaScript, it looks like this:

```
 < div</pre>
class="language-id">is</div><div class='code-container'><code><div class='line'><span
style="color: #0000FF">function</span><span style="color: #000000"> </span><span
style="color: #795E26">sum</span><span style="color: #000000">({ </span><span
style="color: #001080">a</span><span style="color: #000000">, </span><span style="color:
#001080">b</span><span style="color: #000000">, </span><span style="color:
#001080">c</span><span style="color: #000000"> }) {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080">console</span><span
style="color: #000000">.</span><span style="color: #795E26">log</span><span style="color:
#000000">(</span><span style="color: #001080">a</span><span style="color: #000000"> +
</span><span style="color: #001080">b</span><span style="color: #000000"> + </span>
<span style="color: #001080">c</span> <span style="color: #000000">);</span> </div> <div</pre>
class='line'><span style="color: #000000">}</span></div><div class='line'><span style="color:
#795E26">sum</span><span style="color: #000000">({ </span><span style="color:
#001080">a:</span><span style="color: #000000"> </span><span style="color:
#098658">10</span><span style="color: #000000">, </span><span style="color: #001080">b:
</span><span style="color: #000000"> </span><span style="color: #098658">3</span><span
style="color: #000000">, </span><span style="color: #001080">c:</span><span style="color:
#000000"> </span><span style="color: #098658">9</span><span style="color: #000000"> });
</span></div></code></div>
```

The type annotation for the object goes after the destructuring syntax:

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function sum({ a, b, c }: {&#13; a: number;&#13; b: number;&#13; c: number;&#13;}): void' >sum </data-lsp> ({ , , <data-lsp lsp='var a: number' >a </data-lsp lsp='var b: number' >b </data-lsp> <data-lsp lsp='var b: number' >b </data-lsp lsp='var c: number' >c</data-lsp> <data-lsp lsp='(property) a: number' >a </data-lsp ; ; : <data-lsp lsp='(property) b: number' >b </data-lsp> ; :

#267F99">number ; <data-lsp lsp='(property) c: number' >c</data-lsp> ; number <data-lsp lsp='(method)</td>

Console.log(...data: any[]): void' >log</data-lsp> (<data-lsp lsp='var a: number' >a</data-lsp> + <data-lsp lsp='var b: number' >b</data-lsp> <data-lsp lsp='var b: number' >b</data-lsp> <data-lsp lsp='var c: number' >c</data-lsp> ; </div> <div class='line'> ; </div> </div>

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAZxAWwBQG9EEMA0iARoRlgL4 </div>

This can look a bit verbose, but you can use a named type here as well:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #008000">// Same as prior example </div> < div class = 'line' > < span style = "color: #0000FF" > type < span style="color: #000000"> < data-lsp lsp='type ABC = {
 a: number;
 b: number;
 c: number;
}' >ABC < /data-lsp> = { < data-lsp lsp='(property) a: number' >a </data-lsp> < span style="color: #000000">: < span style="color: #267F99">number < span style="color: #000000">; < span style="color: #001080"> <data-lsp lsp='(property) b: number' >b </data-lsp> : number; <data-lsp lsp='(property) c: number' >c</data-lsp>: number };</div><div class='line'> function <span</pre> style="color: #795E26"> < data-lsp lsp='function sum({ a, b, c }: ABC): void' > sum < /data-lsp> ({ < data-lsp lsp='var a: number' >a</data-lsp>, <data-lsp lsp='var b: number' >b </data-lsp> , <data-lsp lsp='var c: number' >c</data-lsp> }: <data-lsp lsp='type ABC = {
 a: number;
 b: number;
 c: number;
}' >ABC </data-lsp>) { </div> <div class='line'> <data-lsp lsp='var</pre> console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp

lsp='var a: number' >a</data-lsp> + <data-lsp lsp='var b: number' >b</data-lsp> + <data-lsp lsp='var c: number' >c</data-lsp> > (span>);</div> <div class='line'> > (span> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEGUEMFsFNUgZ1ABwE4EsD2bSwB4woA2sAUAC4</div>

Assignability of Functions

Return type void

The void return type for functions can produce some unusual, but expected behavior.

Contextual typing with a return type of void does **not** force functions to **not** return something. Another way to say this is a contextual function type with a void return type (type vf = () => void), when implemented, can return *any* other value, but it will be ignored.

Thus, the following implementations of the type () => void are valid:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
voidFunc = () => void' >voidFunc</data-lsp></span><span style="color: #000000"> = ()
</span><span style="color: #0000FF">=&gt;</span><span style="color: #000000"> </span>
<span style="color: #267F99">void</span><span style="color: #000000">;</span></div> <div</pre>
class='line'><span style="color: #0000FF">const</span><span style="color: #000000"> </span>
<span style="color: #795E26"> <data-lsp lsp='const f1: voidFunc' >f1 </data-lsp> </span> <span</pre>
style="color: #000000">: </span> < span style="color: #267F99"> < data-lsp lsp='type voidFunc =
() => void' >voidFunc</data-lsp></span><span style="color: #000000"> = () </span><span
style="color: #0000FF">=&qt;</span><span style="color: #000000"> {</span></div><div
class='line'> < span style="color: #000000"> </span> < span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#0000FF">true</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #000000">};</span></div> <div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='const f2: voidFunc' >f2</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99"> <data-lsp lsp='type voidFunc = () => void'
>voidFunc</data-lsp></span><span style="color: #000000"> = () </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color:
#0000FF">true</span><span style="color: #000000">;</span></div> <div class='line'><span
style="color: #0000FF">const</span><span style="color: #000000"> </span><span style="color:
```

```
#795E26"> <data-lsp lsp='const f3: voidFunc' >f3 </data-lsp> </span> <span style="color: #000000">: </span> <span style="color: #267F99"> <data-lsp lsp='type voidFunc = () => void' >voidFunc </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #000000"> = </span> <span style="color: #00000"> () {</span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #AF00DB"> return </span> <span style="color: #00000"> </span> <span style="color: #0000FF"> true </span> <span style="color: #00000"> ;</span> </div> <div class='line'> <span style="color: #000000"> };</span> </div> <div class='line'> <span style="color: #000000"> };</span> </div> </div> <div class='line'> <span style="color: #000000"> };</span> </div> </div> </div> <div class='line'> <span style="color: #000000"> };</span> </div> </div> </div> </div> <div class='playground-link'</di> href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAbg9gSwCYDECuA7AxlAvFACgEo8A+WR </div>
```

And when the return value of one of these functions is assigned to another variable, it will retain the type of void:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const</span>
<span style="color: #000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const v1:</pre>
void' >v1</data-lsp></span><span style="color: #000000"> = </span><span style="color:
\#795E26" < data-lsp lsp='const f1: () => void' >f1 < /data-lsp> < /span> < span style="color:
#000000">();</span></div> <div class='line'><span style="color: #0000FF">const</span>
<span style="color: #000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const v2:</pre>
void' >v2</data-lsp></span><span style="color: #000000"> = </span><span style="color:
\#795E26" < data-lsp lsp='const f2: () => void' >f2 < /data-lsp> < /span> < span style="color:
#000000">();</span></div> <div class='line'><span style="color: #0000FF">const</span>
<span style="color: #000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const v3:</pre>
void' >v3 </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color:
\#795E26" < data-lsp lsp='const f3: () => void' >f3 < /data-lsp> < /span> < span style="color:
#000000">();</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAbg9gSwCYDECuA7AxlAvFACgEo8A+WR
</div>
```

This behavior exists so that the following code is valid even though Array.prototype.push returns a number and the Array.prototype.forEach method expects a function with a return type of void.

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> const</span> <span style="color: #000000"> </span> <span style="color: #0070C1"> <data-lsp lsp='const src: number[]' >src</data-lsp> </span> <span style="color: #000000"> = [</span> <span style="color: #098658">1</span> <span style="color: #000000">, </span> <span style="color: #098658">2</span> <span style="color: #000000">, </span> <span style="color: #098658">3</span> <span style="color: #000000">];</span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="colo
```

```
\#000000" = [</span><span style="color: \#098658">0</span><span style="color: \#000000">];
</span></div> <div class='line'><span style="color: #001080"><data-lsp lsp='const src:
number[]' >src</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Array&amp;lt;number > .forEach(callbackfn: (value: number,
index: number, array: number[]) => void, thisArg?: any): void' >forEach</data-lsp></span><span
style="color: #000000">((</span><span style="color: #001080"><data-lsp lsp='(parameter) el:
number' >el</data-lsp></span><span style="color: #000000">) </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='const dst: number[]' >dst</data-lsp></span><span style="color: #000000">.
</span><span style="color: #795E26"><data-lsp lsp='(method)
Array<number>.push(...items: number[]): number' > push < /data-lsp> < /span> < span
style="color: #000000">(</span><span style="color: #001080"> < data-lsp lsp='(parameter) el:
number' >el </data-lsp> </span> <span style="color: #000000">)); </span> </div> </code> <a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYewdgzgLgBBBOwYF4YG0CMAaGAmHAzALoDcAUk
</div>
```

There is one other special case to be aware of, when a literal function definition has a void return type, that function must **not** return anything.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>

</div>
```

For more on void please refer to these other documentation entries:

- <u>v1 handbook</u>
- <u>v2 handbook</u>
- FAQ "Why are functions returning non-void assignable to function returning void?"

Object Types

In JavaScript, the fundamental way that we group and pass around data is through objects. In TypeScript, we represent those through *object types*.

As we've seen, they can be anonymous:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
greet(person: {
 name: string;
 age: number;
}): string' > greet < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) person: {
 name: string;
 age: number;
}'
>person</data-lsp></span><span style="color: #000000">: { </span><span style="color:
#001080"> < data-lsp lsp='(property) name: string' > name < /data-lsp > </span> < span style="color:
#000000">; </span> <span style="color: #001080"> <data-lsp lsp='(property) age: number'
>age</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000"> }) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #AF00DB">return</span><span</pre>
style="color: #000000"> </span><span style="color: #A31515"> "Hello "</span><span
style="color: #000000"> + </span><span style="color: #001080"> < data-lsp lsp='(parameter)
person: {
 name: string;
 age: number;
}' >person</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #001080"><data-lsp
lsp='(property) name: string' >name</data-lsp> </span> < span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAcwE4FN1QBQAd2oDOCAXIgN(
</div>
```

or they can be named by using either an interface

```
class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface</span>
<span style="color: #000000"> </span> < span style="color: #267F99"> < data-lsp lsp='interface
Person' > Person</data-lsp> </span> < span style="color: #000000"> {</span> < /div> < div
class='line'> < span style="color: #000000"> </span> < span style="color: #001080"> < data-lsp
lsp='(property) Person.name: string' > name < /data-lsp> </span> < span style="color: #000000">:
</span> < span style="color: #267F99"> string</span> < span style="color: #000000"> ;</span> < span style="color: #001080">
</div> < div class='line'> < span style="color: #000000"> < /span> < span style="color: #001080">
< data-lsp lsp='(property) Person.age: number' > age < /data-lsp < /span> < span style="color: #00000"> : </span> < span style="color: #0
```

#000000">;</div><div class='line'>}</div> <div class='line'>function <data-lsp lsp='function greet(person: Person): string' >greet</data-lsp>(< data-lsp lsp='(parameter) person: Person' > person < /data-lsp > < span style="color: #000000">: < span style="color: #267F99"> < data-lsp lsp='interface Person' >Person</data-lsp>) {</div><div class='line'> return<span</pre> style="color: #000000"> "Hello " + < data-lsp lsp='(parameter) person: Person' > person < /data-lsp > . < data-lsp lsp='(property) Person.name: string' > name < /data-lsp> ;</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgArQM4HsTIN4BQyyA9CcRcg </div>

or a type alias.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type</pre> Person = {
 name: string;
 age: number;
}' >Person < /data-lsp> = { <div> <div class='line'> <data-lsp lsp='(property) name: string' >name</data-lsp>: string;</div><div class='line'> <data-lsp lsp='(property) age: number' >age</data-lsp>: number;</div><div class='line'> };</div> <div class='line'><span style="color:</pre> #0000FF">function < data-lsp lsp='function greet(person: Person): string' > greet < /data-lsp > < span style="color: #000000">(<data-lsp lsp='(parameter) person: Person' >person</data-lsp>: < data-lsp lsp='type Person = {&#13; name: string;&#13; age: number;
}' >Person</data-lsp>) { </div><div class='line'> return "Hello " + < data-lsp lsp='(parameter) person: Person' > person < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(property) name: string' >name</data-lsp>;</div><div class='line'>}</div></code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAChBOBnA9gOygXigbwFBSgHpCoA9ci-KVAQwFsIAuKRYeAS1QHMBuKmrk2oBXOgCMEfAL59cAM2GoAxsHZooXeBAjAAFJCRpmcQ6gCUOKluDI </div>

In all three examples above, we've written functions that take objects that contain the property name (which must be a string) and age (which must be a number).

Property Modifiers

Each property in an object type can specify a couple of things: the type, whether the property is optional, and whether the property can be written to.

Optional Properties

Much of the time, we'll find ourselves dealing with objects that *might* have a property set. In those cases, we can mark those properties as *optional* by adding a question mark (?) to the end of their names.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
PaintOptions' > PaintOptions < /data-lsp > </span > <span style="color: #000000" > {</span > </div >
<div class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-</pre>
lsp lsp='(property) PaintOptions.shape: Shape' >shape</data-lsp></span><span style="color:</pre>
#000000">: </span><span style="color: #267F99"> < data-lsp lsp='interface Shape'

```

In this example, both xPos and yPos are considered optional. We can choose to provide either of them, so every call above to paintShape is valid. All optionality really says is that if the property *is* set, it better have a specific type.

```
lsp lsp='(property) PaintOptions.shape: Shape' >shape</data-lsp></span><span style="color:
#000000">: </span><span style="color: #267F99"> < data-lsp lsp='interface Shape'

```

In JavaScript, even if the property has never been set, we can still access it - it's just going to give us the value undefined. We can just handle undefined specially.

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function paintShape(opts: PaintOptions): void' > paintShape </data-lsp > (<data-lsp lsp='(parameter) opts: PaintOptions' > opts </data-lsp> : <data-lsp lsp='interface PaintOptions' > PaintOptions </data-lsp> (</div> <div class='line'>

style="color: #001080"> < data-lsp lsp='(parameter) opts: PaintOptions' > opts < /data-lsp > .<data-lsp lsp='(property)</pre> PaintOptions.xPos?: number | undefined' >xPos</data-lsp> === <data-lsp lsp='var undefined' >undefined</data-lsp>? 0: <data-lsp lsp='(parameter) opts: PaintOptions' >opts</data-lsp><span style="color:</pre> #000000">.<data-lsp lsp='(property) PaintOptions.xPos?: number' >xPos</data-lsp>;</div> < div class='arrow'> </div>let xPos: number <div class='line'> let <data-lsp lsp='let yPos: number' style='border-bottom: solid 2px lightgrey;'>yPos</data-lsp> = <data-lsp lsp='(parameter) opts: PaintOptions' > opts < /data-lsp> < /span> < span style="color: #000000">. <data-lsp lsp='(property) PaintOptions.yPos?: number | undefined' >yPos</data-lsp> === < data-lsp lsp='var undefined' > undefined < /data-lsp > < span style="color: #000000">? 0: < data-lsp lsp='(parameter) opts: PaintOptions' > opts </data-lsp > . < data-lsp lsp='(property) PaintOptions.yPos?: number' >yPos</data-lsp> ;</div> <div class='arrow'> </div> let yPos: number <div class='line'> // ...</div><div</pre> class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMoAs4AcUG8C+AUACYQIA2 </div>

Note that this pattern of setting defaults for unspecified values is so common that JavaScript has syntax to support it.

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function paintShape({ shape, xPos, yPos }: PaintOptions): void' > paintShape</data-lsp > ({ <data-lsp lsp='var shape: Shape' >shape</data-lsp> , <data-lsp lsp='var xPos: number' >xPos</data-lsp> , , <span style="color:

```
>log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"x coordinate at"</span><span style="color: #000000">, </span><span style="color:
#001080"> < data-lsp lsp='var xPos: number' style='border-bottom: solid 2px
lightgrey;'>xPos</data-lsp></span><span style="color: #000000">);</span></div><span
class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>var xPos:
number</span> <div class='line'><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span > < span style="color:
#000000">.</span><span style="color: #795E26"><data-lsp lsp='(method) Console.log(...data:
any[]): void' >log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"y coordinate at"</span><span style="color: #000000">, </span><span style="color:
#001080"> < data-lsp lsp='var yPos: number' style='border-bottom: solid 2px
lightgrey;'>yPos</data-lsp></span><span style="color: #000000">);</span></div><span
class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>var yPos:
number</span> <div class='line'> <span style="color: #000000"> </span> <span style="color:
#008000">// ...</span></div><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMoAs4AcUG8C+AUACYQIA2
```

<div class='line'> <data-</pre>

lsp lsp='var console: Console' >console</data-lsp>. <data-lsp lsp='(method) Console.log(...data: any[]): void'

Here we used <u>a destructuring pattern</u> for paintShape 's parameter, and provided <u>default values</u> for xPos and yPos. Now xPos and yPos are both definitely present within the body of paintShape, but optional for any callers to paintShape.

U2t7Z3d-QA9Ww6unv7Bkc9x5knpkFmUBYqfVfMNvfeP5EPX8N6-wnwQA'>Try</div>

Note that there is currently no way to place type annotations within destructuring patterns. This is because the following syntax already means something different in JavaScript.

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function draw({ shape: Shape, xPos: number }: {&#13; shape: any;&#13; xPos?: number | undefined;&#13;}): void' >draw </data-lsp> <data-lsp lsp='(property) shape: any' >shape </data-lsp> <data-lsp lsp='(property) shape: any' >shape </data-lsp lsp='var Shape: any' >Shape </data-lsp> <data-lsp lsp='(property) xPos?: number | undefined' >xPos </data-lsp lsp='color: #001080"> <data-lsp lsp='(property) xPos?: number | undefined' >xPos </data-lsp lsp='var number: number' >number </data-lsp> </s

lsp lsp='function render(x: unknown): any' > render < /data-lsp > < span style="color:</pre> #000000">(<data-err><data-lsp lsp='any' >shape</datalsp></data-err>);</div> Cannot find name 'shape'. Did you mean 'Shape'?<span</pre> class="code">2552Cannot find name 'shape'. Did you mean 'Shape'?<div class='line'> < data-lsp lsp='function render(x: unknown): any' > render < /data-lsp> (<data-err> <data-lsp lsp='any' >xPos</data-lsp></data-err>); </div>Cannot find name 'xPos'.2304Cannot find name 'xPos'. <div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEDsHsEkFsAOAbAlgY1QFwIKQJ4BcoAZqIbIDOA </div>

In an object destructuring pattern, shape: Shape means "grab the property shape and redefine it locally as a variable named Shape. Likewise xPos: number creates a variable named number whose value is based on the parameter's xPos.

readonly Properties

Properties can also be marked as readonly for TypeScript. While it won't change any behavior at runtime, a property marked as readonly can't be written to during type-checking.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> SomeType' >SomeType</data-lsp> {</div><div class='line'> < span style="color: #000000"> < span style="color: #0000FF">readonly < data-lsp lsp='(property) SomeType.prop: string' > prop < /data-lsp > < span style="color: #000000">: string;</div><div class='line'>} </div> <div class='line'>function < data-lsp lsp='function doSomething(obj: SomeType): void' >doSomething</data-lsp>(<data-lsp lsp='(parameter) obj: SomeType' >obj</data-lsp>: <data-lsp lsp='interface SomeType' >SomeType</data-lsp><span style="color:</pre> #000000">) {</div><div class='line'> // We can read from 'obj.prop'.</div><div class='line'> < span style="color: #000000"> < span style="color: #001080"> < data-lsp

```
lsp='var console: Console' >console</data-lsp></span><span style="color: #000000">.</span>
<span style="color: #795E26"> <data-lsp lsp='(method) Console.log(...data: any[]): void'</pre>
>log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">`prop has the value '</span><span style="color: #0000FF">${</span><span
style="color: #001080"> < data-lsp lsp='(parameter) obj: SomeType' > obj < /data-lsp > </span>
<span style="color: #000000FF">.</span><span style="color: #001080"><data-lsp</pre>
lsp='(property) SomeType.prop: string' >prop</data-lsp></span><span style="color: #0000FF">}
</span><span style="color: #A31515">&apos;.`</span><span style="color: #000000">);</span>
</div> <div class='line'> <span style="color: #000000"> </span> <span style="color:
#008000">// But we can't re-assign it.</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) obj: SomeType'
>obj</data-lsp></span><span style="color: #000000">.</span><span style="color: #001080">
<data-err> <data-lsp lsp='(property) SomeType.prop: string' >prop</data-lsp> </data-err>
</span><span style="color: #000000"> = </span><span style="color: #A31515"> "hello" </span>
<span style="color: #000000">;</span></div><span class="error"><span>Cannot assign to
'prop' because it is a read-only property.</span><span class="code">2540</span></span>
<span class="error-behind">Cannot assign to 'prop' because it is a read-only property.</span>
<div class='line'><span style="color: #000000">}</span></div></code><a class='playground-</pre>
link'
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYAsAGAUAJYB2ALjAGYC@IBqcUQ4CUgkiTgVWwADVM5QK0pEUGs6ADdKCT06OIASHkSUuU0Mss8NLP8AIT0SUAB3YNC4yaEAWI </div>

Using the readonly modifier doesn't necessarily imply that a value is totally immutable - or in other words, that its internal contents can't be changed. It just means the property itself can't be rewritten to.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>

```

It's important to manage expectations of what readonly implies. It's useful to signal intent during development time for TypeScript on how an object should be used. TypeScript doesn't factor in whether properties on two types are readonly when checking whether those types are compatible, so readonly properties can also change via aliasing.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>

Index Signatures

Sometimes you don't know all the names of a type's properties ahead of time, but you do know the shape of the values.

In those cases you can use an index signature to describe the types of possible values, for example:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
StringArray' > StringArray < /data-lsp > </span > < span style="color: #000000" > { </span > < /div >
<div class='line'><span style="color: #000000"> [</span><span style="color: #001080"> <data-</pre>
lsp lsp='(parameter) index: number' >index</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99">number</span><span style="color: #000000">]: </span>
<span style="color: #267F99">string</span><span style="color: #000000">;</span></div><div</pre>
class='line'><span style="color: #000000">}</span></div> <div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const myArray: StringArray' >myArray</data-lsp></span><span style="color:
#000000">: </span> <span style="color: #267F99"> <data-lsp lsp='interface StringArray'
>StringArray</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#795E26"> < data-lsp lsp='function getStringArray(): StringArray' > getStringArray < /data-lsp>
</span><span style="color: #000000">();</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const secondItem: string' style='border-bottom: solid 2px</pre>
lightgrey;'>secondItem</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #001080"> < data-lsp lsp='const myArray: StringArray' > myArray < /data-lsp>
<span> <span style="color: #000000">[</span> <span style="color: #098658">1</span> <span
style="color: #000000">];</span></div><span class='popover-prefix'> </span><span
class='popover'> < div class='arrow'> </div> const secondItem: string </span> </code> < a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEAzArgOzAFwJYHtXwHMQMBIDGLV.
qbBl5GDk0eHQZ4AF5CYnDtPlYhP1QAl3A8YABJJRsYwODl4wBGRyFRlygAPQB+IA'>Try</a></div>
```

Above, we have a StringArray interface which has an index signature. This index signature states that when a StringArray is indexed with a number, it will return a string.

An index signature property type must be either 'string' or 'number'.

```
#267F99">string</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #000000">}</span></div> <div class='line'><span style="color:

lsp></span><span style="color: #000000">;</span></div><div class='line'><span style="color:
#000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwBYCMBmAUCBlgC7QCWA
</div> </details>
```

While string index signatures are a powerful way to describe the "dictionary" pattern, they also enforce that all properties match their return type. This is because a string index declares that obj.property is also available as obj["property"]. In the following example, name 's type does not match the string index's type, and the type checker gives an error:

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface
 < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='interface
 NumberDictionary' > NumberDictionary < / data-lsp> < / span> < span style="color: #000000">
 { < / div> < div class='line'> < span style="color: #000000"> [< / span> < span style="color: #001080"> < data-lsp lsp='(parameter) index: string' > index < / data-lsp> < / span> < span
 style="color: #000000">: < / span> < span style="color: #267F99"> string < / span> < span
</pre>

```
style="color: #000000">]: </span> <span style="color: #267F99">number </span> <span style="color: #000000">; </span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(property) NumberDictionary.length: number' >length </data-lsp> </span> <span style="color: #000000">: </span> <span style="color: #000000">: </span> <span style="color: #000000">; </span> <span style="color: #000000"> : </span> <span class="error"> <span> Property 'name' of type 'string' is not assignable to string index type 'number'. </span> <span class="error"> div class='line'> <span style="color: #000000"> : </span> <span class="error-behind"> Property 'name' of type 'string' is not assignable to string index type 'number'. </span> <div class='line'> <span style="color: #000000"> : </span> </div> </code> <a class='playground-link'
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwBYCMWBQIIZ4IVMdcBLAC</div>

However, properties of different types are acceptable if the index signature is a union of the property types:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
NumberOrStringDictionary' > NumberOrStringDictionary < /data-lsp > </span > <span style="color:
#000000"> {</span></div><div class='line'><span style="color: #000000"> [</span><span
style="color: #001080"> < data-lsp lsp='(parameter) index: string' > index < /data-lsp > </span>
<span style="color: #000000">: </span><span style="color: #267F99">string</span><span</pre>
style="color: #000000">]: </span><span style="color: #267F99">number</span><span
style="color: #000000"> | </span><span style="color: #267F99">string</span><span
style="color: #000000">;</span></div><div class='line'><span style="color: #000000">
</span> < span style="color: #001080"> < data-lsp lsp='(property)
NumberOrStringDictionary.length: number' >length </data-lsp> </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F9999"> number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999</span style="c
#000000">; </span> <span style="color: #008000">// ok, length is a number </span> </div> <div
class='line'> < span style="color: #000000"> </span> < span style="color: #001080"> < data-lsp
lsp='(property) NumberOrStringDictionary.name: string' >name</data-lsp></span><span
style="color: #000000">: </span><span style="color: #267F99">string</span><span
style="color: #000000">; </span><span style="color: #008000">// ok, name is a string</span>
</div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgHIFcC2AjaB5KAZTCIAHMARY
```

Finally, you can make index signatures readonly in order to prevent assignment to their indices:

</div>

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
ReadonlyStringArray' > ReadonlyStringArray < /data-lsp> < /span> < span style="color: #000000">
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#0000FF">readonly</span><span style="color: #000000"> [</span><span style="color:
#001080"> < data-lsp lsp='(parameter) index: number' > index < /data-lsp > < /span > < span
style="color: #000000">: </span><span style="color: #267F99">number</span><span
style="color: #000000">]: </span><span style="color: #267F99">string</span><span
style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span> </div> <div class='line'> <span style="color: #0000FF">let</span> <span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='let myArray:
ReadonlyStringArray' >myArray</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='interface ReadonlyStringArray'</pre>
>ReadonlyStringArray</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #795E26"> < data-lsp lsp='function getReadOnlyStringArray(): ReadonlyStringArray'
>getReadOnlyStringArray</data-lsp></span><span style="color: #000000">();</span></div>
<div class='line'><span style="color: #001080"><data-lsp lsp='let myArray: ReadonlyStringArray'
>myArray</data-lsp></span><span style="color: #000000">[</span><span style="color:
#A31515">"Mallory"</span><span style="color: #000000">;</span></div><span
class="error"> < span> Index signature in type 'ReadonlyStringArray' only permits reading. </span>
<span class="code">2542</span></span><span class="error-behind">Index signature in type
'ReadonlyStringArray' only permits reading.</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxqNqhqTiAEAzArqOzAFwJYHtXwHMQMAIEKYAe
GX4FCsboi0z4FoAiAFkoCAgTWIHZIA'>Try</a></div>
```

You can't set myArray[2] because the index signature is readonly.

Extending Types

It's pretty common to have types that might be more specific versions of other types. For example, we might have a <code>BasicAddress</code> type that describes the fields necessary for sending letters and packages in the U.S.

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface </ span> < span style="color: #000000"> </ span> < span style="color: #267F99"> < data-lsp lsp='interface BasicAddress' > BasicAddress < / data-lsp> < / span> < span style="color: #000000"> { < / span> < / div > < div class='line'> < span style="color: #001080"> < data-lsp lsp='(property) BasicAddress.name?: string | undefined' > name < / data-lsp> < / span> < span style="color: #000000"> ?: < / span> < span style="color: #267F99"> string < / span> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < / div > < div class='line'> < span style="color: #000000"> ; < / span> < span style="color: #000000"> ; < / span style="color: #00000
```

<data-lsp lsp='(property) BasicAddress.street: string' >street</data-lsp>: string;</div><div class='line'> <data-lsp lsp='(property) BasicAddress.city: string' >city </data-lsp> : string;</div><div class='line'> <data-lsp lsp='(property) BasicAddress.country: string' > country < /data-lsp> < /span> < span style="color: #000000">: string string string string string string #000000">;</div><div class='line'> < data-lsp lsp='(property) BasicAddress.postalCode: string' >postalCode</data-lsp>: string;</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEJwM7AQQQCZ5QQYbIDeAl </div>

In some situations that's enough, but addresses often have a unit number associated with them if the building at an address has multiple units. We can then describe an AddressWithUnit.

<!-- prettier-ignore --> class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF">interface < data-lsp lsp='interface AddressWithUnit' > AddressWithUnit < /data-lsp> {</div><div class='line'> <data-lsp lsp='(property) AddressWithUnit.name?: string | undefined' > name < /data-lsp > < span style="color: #000000">?: string < span style="color: #267F99" > string style="color: #267F999" > string style="color: #267F99" > string style="color: #267F999" > stri #000000">;</div><div class='line'> < data-lsp lsp='(property) AddressWithUnit.unit: string' > unit < /data-lsp> : string ;</div><div class='line'> <data-lsp lsp='(property) AddressWithUnit.street: string' >street</data-lsp>: string;</div><div class='line'> <data-lsp lsp='(property) AddressWithUnit.city: string' > city < /data-lsp > < span style="color: #000000">: string;</div><div</pre> class='line'> <data-lsp lsp='(property) AddressWithUnit.country: string' >country</data-lsp>;</div><div class='line'> < data-lsp lsp='(property) AddressWithUnit.postalCode: string'

>postalCode</data-lsp>: string;</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgIIBN1QgZxwdWDAAsBVEI5A </div>

This does the job, but the downside here is that we had to repeat all the other fields from BasicAddress when our changes were purely additive. Instead, we can extend the original BasicAddress type and just add the new fields that are unique to AddressWithUnit.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> BasicAddress' > BasicAddress < /data-lsp > < span style="color: #000000" > { < /div > <div class='line'> <data-</pre> lsp lsp='(property) BasicAddress.name?: string | undefined' >name</data-lsp>?: string;</div><div class='line'> <data-lsp lsp='(property) BasicAddress.street: string' >street</data-lsp>: string;</div><div class='line'> <data-lsp lsp='(property) BasicAddress.city: string' > city < /data-lsp > : string;</div><div class='line'> < span style="color: #000000"> < span style="color: #001080"> < data-lsp lsp='(property) BasicAddress.country: string' > country < /data-lsp> < /span> < span style="color: #000000">;</div><div class='line'> < data-lsp lsp='(property) BasicAddress.postalCode: string' >postalCode</data-lsp>: string;</div><div class='line'>}</div> <div class='line'>interface < data-lsp lsp='interface AddressWithUnit' > AddressWithUnit < /data-lsp > < /span> extends<span</pre> style="color: #000000"> <data-lsp lsp='interface BasicAddress' > BasicAddress < /data-lsp > < span style="color: #000000" > { < /div > <div class='line'> <data-</pre> lsp lsp='(property) AddressWithUnit.unit: string' >unit</data-lsp>;</div><div class='line'>}</div> </code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEJwM7AQQQCZ5QQYbIDeAl</div>

The extends keyword on an interface allows us to effectively copy members from other named types, and add whatever new members we want. This can be useful for cutting down the amount of type declaration boilerplate we have to write, and for signaling intent that several different declarations of the same property might be related. For example, AddressWithUnit didn't need to repeat the street property, and because street originates from BasicAddress, a reader will know that those two types are related in some way.

interface s can also extend from multiple types.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
Colorful' >Colorful</data-lsp></span><span style="color: #000000"> {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) Colorful.color: string' >color</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99">string</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000">}</span></div> <div class='line'><span

style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)
Circle.radius: number' >radius</data-lsp>:</span><span style="color: #000000"> </span><span
```

style="color: #098658">42 , </div> <div class='line'> }; </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMIHsA27YFdPIDeAUMsgljgF: </div>

Intersection Types

interface s allowed us to build up new types from other types by extending them. TypeScript provides another construct called *intersection types* that is mainly used to combine existing object types.

An intersection type is defined using the & operator.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> Colorful' >Colorful</data-lsp> {</div><div class='line'> <data-lsp lsp='(property) Colorful.color: string' >color</data-lsp>: string; </div><div class='line'>}</div><div class='line'>interface < data-lsp lsp='interface Circle' > Circle < /data-lsp> < /span> < span style="color: #000000"> {</div><div class='line'> <data-lsp lsp='(property) Circle.radius: number' >radius</data-lsp>: number;</div><div class='line'> }</div> <div class='line'><span style="color:</pre> #0000FF">type <data-lsp lsp='type ColorfulCircle = Colorful & amp;amp; Circle' > ColorfulCircle < /data-lsp> = < data-lsp lsp='interface Colorful' >Colorful</data-lsp> & < data-lsp lsp='interface Circle' > Circle < /data-lsp > <</pre> style="color: #000000">;</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgMIHsA27YFdPIDeAUMsgljgF: </div>

Here, we've intersected Colorful and Circle to produce a new type that has all the members of Colorful and Circle.

< div class='code-container'> < code> < div class='line'> < span style="color: #00000FF"> function < / span> < span style="color: #795E26"> < data-lsp lsp='function</pre>

Did you mean to write 'radius'?</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAJYB2ALjAGYC</div>

Interfaces vs. Intersections

We just looked at two ways to combine types which are similar, but are actually subtly different. With interfaces, we could use an extends clause to extend from other types, and we were able to do something similar with intersections and name the result with a type alias. The principle difference between the two is how conflicts are handled, and that difference is typically one of the main reasons why you'd pick one over the other between an interface and a type alias of an intersection type.

<!-- For example, two types can declare the same property in an interface. TODO -->

Generic Object Types

Let's imagine a Box type that can contain any value - string s, number s, Giraffe s, whatever.

Right now, the contents property is typed as any, which works, but can lead to accidents down the line.

We could instead use unknown, but that would mean that in cases where we already know the type of contents, we'd need to do precautionary checks, or use error-prone type assertions.

 < div class='code-container'> < code> < div class='line'> < span style="color: #00000FF"> interface < / span> < span style="color: #267F99"> < data-lsp lsp='interface</pre>

href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEIHsAeyDeAoZZBdcCcAZwC5
</div>
```

One type safe approach would be to instead scaffold out different Box types for every type of contents .

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
NumberBox' > NumberBox < /data-lsp > </span > <span style="color: #000000" > { </span > </div >
<div class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-</pre>
lsp lsp='(property) NumberBox.contents: number' >contents</data-lsp></span><span
style="color: #000000">: </span><span style="color: #267F99">number</span><span
style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div> <div class='line'><span style="color: #0000FF">interface</span><span
style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface
StringBox' > StringBox</data-lsp></span><span style="color: #000000"> {</span></div><div
class='line'> < span style="color: #000000"> </span> < span style="color: #001080"> < data-lsp
lsp='(property) StringBox.contents: string' > contents < /data-lsp> < /span> < span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'> < span style="color: #0000FF">interface < / span > < span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='interface BooleanBox' >BooleanBox</data-
lsp></span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)
BooleanBox.contents: boolean' >contents</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99">boolean</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGY1oFAEsA7AFxgDMBDAY
</div>
```

But that means we'll have to create different functions, or overloads of functions, to operate on these types.

```
style="color: #000000"> </span><span style="color: #795E26"> < data-lsp lsp='function
setContents(box: NumberBox, newContents: number): void (+2 overloads)' > setContents < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) box: NumberBox' >box</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99"><data-lsp lsp='interface NumberBox' > NumberBox</data-
lsp></span><span style="color: #000000">, </span><span style="color: #001080"><data-lsp
lsp='(parameter) newContents: number' > newContents < /data-lsp> < /span> < span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F999999
#000000">): </span> < span style="color: #267F99"> void </span> < span style="color: #000000">;
</span></div><div class='line'><span style="color: #0000FF">function</span><span
style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function
setContents(box: BooleanBox, newContents: boolean): void (+2 overloads)' > setContents < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) box: BooleanBox' >box</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99"><data-lsp lsp='interface BooleanBox' > BooleanBox</data-
lsp></span><span style="color: #000000">, </span><span style="color: #001080"><data-lsp
lsp='(parameter) newContents: boolean' > newContents < /data-lsp> < /span> < span style="color:

style="color: #267F99">any</span><span style="color: #000000"> }, </span><span style="color:
#001080"> < data-lsp lsp='(parameter) newContents: any' > newContents < /data-lsp > </span>
<span style="color: #000000">: </span><span style="color: #267F99">any</span><span</pre>
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='(parameter) box: {&amp;#13; contents:
any;
}' >box</data-lsp></span><span style="color: #000000">.</span><span
style="color: #001080"> < data-lsp lsp='(property) contents: any' > contents < /data-lsp > </span>
<span style="color: #000000"> = </span><span style="color: #001080"> < data-lsp</pre>
lsp='(parameter) newContents: any' > newContents < /data-lsp> < /span> < span style="color:</pre>
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgHIFcC2AjaAhAewA9kBvAKGV
</div>
```

That's a lot of boilerplate. Moreover, we might later need to introduce new types and overloads. This is frustrating, since our box types and overloads are all effectively the same.

Instead, we can make a *generic* Box type which declares a *type parameter*.

<div class='code-container'> <code> <div class='line'> interface <data-lsp lsp='interface Box&lt;Type>' > Box</data-lsp> < < <data-lsp lsp='(type parameter) Type in Box&lt;Type>' > Type</data-lsp> > { </div> <div class='line'> <data-lsp lsp='(property) Box&lt;Type>.contents: Type' > contents </data-lsp> : : ; </div> <div class='line'> ; </div> <div class='line'> ; </div> </div> <div class='line'> ; </div> </div> <div class='line'> </div> </div>

href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEIHsAeAeAKgTwAcIA+ZAbw(</div>

You might read this as $\hat{a} \in A$ Box of Type is something whose contents have type $\hat{a} \in A$. Later on, when we refer to Box, we have to give a *type argument* in place of Type.

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span> < span
style="color: #000000"> < / span> < span style="color: #001080"> < data-lsp lsp='let box:
Box&lt;string>' > box</data-lsp> < / span> < span style="color: #000000"> : < / span> < span
style="color: #267F99"> < data-lsp lsp='interface Box&lt;Type>' > Box</data-lsp> < / span> < span style="color: #000000"> & lt; < / span> < span style="color: #267F99"> string < / span> < span
style="color: #000000"> & gt;; < / span> < / div> < / code> < a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEIHsAeAeAKgTwAcIA+ZAbw(
< / div>

Think of Box as a template for a real type, where Type is a placeholder that will get replaced with some other type. When TypeScript sees Box<string>, it will replace every instance of Type in Box<Type> with string, and end up working with something like { contents: string }. In other words, Box<string> and our earlier StringBox work identically.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface </ span> < span style="color: #000000"> </ span> < span style="color: #267F99"> < data-lsp lsp='interface Box&lt;Type>'> Box</data-lsp > </ span> < span style="color: #000000"> & lt; </ span> < span style="color: #000000"> < span style="color: #000000"> < span style="color: #001080"> < data-lsp lsp='(property) Box&lt;Type> .contents: Type' > contents < /data-lsp | sp='(type parameter) Type in</pre>

```
Box<Type>' >Type</data-lsp></span><span style="color: #000000">;</span></div>
<div class='line'><span style="color: #000000">}</span></div><div class='line'><span</pre>
style="color: #0000FF">interface</span><span style="color: #000000"> </span><span

href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEIHsAeAeAKgTwAcIA+ZAbw(
</div>
```

Box is reusable in that Type can be substituted with anything. That means that when we need a box for a new type, we don't need to declare a new Box type at all (though we certainly could if we wanted to).

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> Box<Type>' >Box</data-lsp>< < data-lsp lsp='(type parameter) Type in Box&lt;Type>' > Type < /datalsp>&qt; {</div><div class='line'> <data-lsp lsp='(property) Box<Type>.contents: Type' > contents < /data-lsp> < /span> < span style="color: #000000">: <data-lsp lsp='(type parameter) Type in Box<Type>' >Type</data-lsp> ; </div> <div class='line'>}</div> <div class='line'><span</pre> style="color: #0000FF">interface < data-lsp lsp='interface Apple' > Apple < /data-lsp > < span style="color: #000000"> {</div><div class='line'> //</div><div class='line'>}</div> <div class='line'>// Same as '{ contents: Apple }'.</div><div class='line'>type <data-lsp lsp='type AppleBox = Box&lt;Apple>' >AppleBox</data-lsp><span</pre> style="color: #000000"> = < data-lsp lsp='interface Box<Type>' >Box</data-lsp>< < data-lsp lsp='interface Apple' > Apple < /data-lsp > < span style="color: #000000">>;</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEIHsAeAeAKgTwAcIA+ZAbw(</div>

This also means that we can avoid overloads entirely by instead using generic functions.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> setContents<Type>(box: Box&lt;Type>, newContents: Type): void' > setContents < /datalsp><<data-lsp lsp='(type parameter) Type in setContents<Type>(box: Box&lt;Type>, newContents: Type): void' >Type</data-lsp> < span style="color: #000000"> &qt;(< span style="color: #001080"> < data-lsp lsp='(parameter) box: Box&lt;Type>' > box < /data-lsp> : < data-lsp lsp='interface Box<Type>' >Box</data-lsp>< < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in setContents<Type>(box: Box&lt;Type>, newContents: Type): void' > Type < /data-lsp> >, <data-lsp lsp='(parameter) newContents: Type' > newContents < /data-lsp> < /span> < span style="color: #000000">: <data-lsp lsp='(type parameter) Type in setContents<Type>(box: Box&lt;Type>, newContents: Type): void' >Type</data-lsp>

```
</span> <span style="color: #000000">) {</span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) box:
Box&amp;lt;Type>' > box</data-lsp> </span> <span style="color: #000000">.</span> <span style="color: #000000">.</span> <span style="color: #001080"> <data-lsp lsp='(property) Box&amp;lt;Type>.contents: Type'
>contents </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #001080"> <data-lsp lsp='(parameter) newContents: Type' >newContents </data-lsp> </span> </span> </span> </div> <data-lsp lsp='(parameter) newContents: Type' >newContents </data-lsp> </span> </span> </div> <data-lsp lsp='(parameter) newContents: Type' >newContents </data-lsp> </span> </span> </div> </span> </div> <div class='line'> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #000000"> ;</span> </div> </div> </div> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgEIHsAeAeAKgTwAcIA+ZAbw( </div>
```

It is worth noting that type aliases can also be generic. We could have defined our new Box<Type> interface, which was:

<div class='code-container'> <code> <div class='line'> interface <data-lsp lsp='interface Box&lt;Type>' > Box</data-lsp> < < <data-lsp lsp='(type parameter) Type in Box&lt;Type>' > Type</data-lsp> > { </div> <div class='line'> <data-lsp lsp='(property) Box&lt;Type> .contents: Type' > contents </data-lsp> : : : : </div> <div class='line'> ; </div> <div class='line'> ; </div> </div> <div class='line'> ; </div> </div>

href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgElHsAeAeAKgTwAcIA+ZAbw(</div>

by using a type alias instead:

<div class='code-container'> <code> <div class='line'> type <data-lsp lsp='type Box&lt;Type> = {&#13; contents: Type;&#13;}' > Box</data-lsp > < <data-lsp lsp='(type parameter) Type in type Box&lt;Type>' > Type</data-lsp> > = { </div> <div class='line'> <data-lsp lsp='(property) contents: Type' > contents </data-lsp | sp='(type parameter) Type in type Box&lt;Type>' > Type</data-lsp> <data-lsp lsp='(type parameter) Type in type Box&lt;Type>' > Type</data-lsp> ; </div> <div class='line'> }; </div> <div class='line'> }; </div> <div class='line'> }; </div> </div> <div class='line'> }; </div> </div> <div class='line'> };

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAQg9gDwDwBVwQHxQLxQN4BQUUAxn/
</div>

Since type aliases, unlike interfaces, can describe more than just object types, we can also use them to write other kinds of generic helper types.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
OrNull<Type> = Type | null' >OrNull</data-lsp></span><span style="color:

```

<div class='arrow'></div>type OneOrManyOrNullStrings = OneOrMany<string> |
null</code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDsGBQAXATwAdJQB5a/
</div>

We'll circle back to type aliases in just a little bit.

The Array Type

Generic object types are often some sort of container type that work independently of the type of elements they contain. It's ideal for data structures to work this way so that they're re-usable across different data types.

It turns out we've been working with a type just like that throughout this handbook: the Array type. Whenever we write out types like <code>number[]</code> or <code>string[]</code>, that's really just a shorthand for <code>Array<number></code> and <code>Array<string></code>.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> doSomething(value: Array<string>): void' >doSomething</data-lsp>(<data-lsp lsp='(parameter) value: string[]' >value</data-lsp>: < data-lsp lsp='interface Array&lt;T>' > Array < /data-lsp> < /span> < span style="color: #000000"><string>) {</div><div class='line'> // ...</div><div class='line'>}</div> <div class='line'>let <data-lsp lsp='let myArray: string[]' >myArray</data-lsp>: string[] = ["hello" < span style="color: #000000">, < span style="color: #A31515">"world"];</div> <div class='line'>// either of these work!</div><div class='line'> < span style="color: #795E26"> < data-lsp lsp='function doSomething(value: Array<string>): void' > doSomething < /data-lsp> < /span> < span style="color: #000000"> (<data-lsp lsp='let myArray: string[]' >myArray </datalsp>);</div><div class='line'> < data-lsp lsp='function doSomething(value: Array&lt;string>): void' >doSomething</data-lsp>(new <data-lsp lsp='var Array: ArrayConstructor&#13;new &lt;string>(...items: string[]) => string[] (+2 overloads)' >Array</data-lsp>(<span

style="color: #A31515"> "hello" < span style="color: #000000">, < span style="color: #A31515"> "world" < span style="color: #000000">)); </div> </code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAEzgZTgWwKZQBYxgDmAFAG4CW2ESoA'>Try</div>

Much like the Box type above, Array itself is a generic type.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> Array<Type>' > Array </data-lsp> < span style="color: #000000">< < data-lsp lsp='(type parameter) Type in Array&lt;Type>' >Type</data-lsp>&qt; {</div><div class='line'> /**</div><div</pre> class='line'> * Gets or sets the length of the array.</div> <div class='line'> */</div><div class='line'><span</pre> style="color: #000000"> <data-lsp lsp='(property) Array<Type>.length: number' >length</data-lsp>: number; </div> <div class='line'> /**</div><div class='line'> * Removes the last element from an array and returns it.</div><div class='line'> */ </div> <div class='line'> < data-lsp lsp='(method) Array&lt;Type>.pop(): Type | undefined' >pop</data-lsp>(): < data-lsp lsp='(type parameter) Type in Array&lt;Type>' > Type < /data-lsp> | undefined;</div> <div class='line'> /** </div> <div class='line'> * Appends new elements to an array, and returns the new length of the array.</div><div class='line'> */</div><div class='line'> < data-lsp lsp='(method) Array&lt;Type>.push(...items: Type[]): number' >push</data-lsp>(... < data-lsp lsp='(parameter) items: Type[]' > items < /data-lsp > < span style="color: #000000">: < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in Array<Type>' >Type</data-lsp>[]): number; </div> <div class='line'> // ...</div><div class='line'>}</div> </code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/PTAEAEDsHsBkEsBGAuUAXATgVwKYCh5I0cMAzAQwG </div>

Modern JavaScript also provides other data structures which are generic, like Map<K, V>, Set<T>, and Promise<T>. All this really means is that because of how Map, Set, and Promise behave, they can work with any sets of types.

The ReadonlyArray Type

The ReadonlyArray is a special type that describes arrays that shouldn't be changed.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
doStuff(values: ReadonlyArray<string>): void' >doStuff</data-lsp></span><span
style="color: #000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter)
values: readonly string[]' >values</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='interface ReadonlyArray&amp;lt;T>'
>ReadonlyArray</data-lsp></span><span style="color: #000000">&It;</span><span
style="color: #267F99">string</span><span style="color: #000000">&gt;) {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #008000">// We can
read from 'values'...</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #0000FF">const</span><span style="color: #000000"> </span>
<span style="color: #0070C1"> <data-lsp lsp='const copy: string[]' > copy </data-lsp> </span>
<span style="color: #000000"> = </span><span style="color: #001080"> < data-lsp</pre>
lsp='(parameter) values: readonly string[]' >values</data-lsp></span><span style="color:</pre>
#000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
ReadonlyArray<string>.slice(start?: number | undefined, end?: number | undefined): string[]'
>slice</data-lsp></span><span style="color: #000000">();</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='var</pre>
console: Console' >console</data-lsp></span><span style="color: #000000">.</span><span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #A31515">`The first value is
</span><span style="color: #0000FF">${</span><span style="color: #001080"><data-lsp
lsp='(parameter) values: readonly string[]' >values</data-lsp></span><span style="color:</pre>
#000000FF">[</span><span style="color: #098658">0</span><span style="color:
#000000FF">]</span><span style="color: #0000FF">}</span><span style="color:
#A31515">`</span><span style="color: #000000">);</span></div> <div class='line'><span
style="color: #000000"> </span><span style="color: #008000">// ...but we can&apos;t mutate
'values'.</span></div><div class='line'><span style="color: #000000"> </span>
<span style="color: #001080"> <data-lsp lsp='(parameter) values: readonly string[]'</pre>
>values</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-err> < data-lsp lsp='any' > push < /data-lsp> < /data-err> < /span> < span
```

style="color: #000000">("hello!"); </div> Property 'push' does not exist on type 'readonly string[]'. 2339 Property 'push' does not exist on type 'readonly string[]'. <div class="line"> } </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQAzAVwDsBjAFw </div>

Much like the readonly modifier for properties, it's mainly a tool we can use for intent. When we see a function that returns ReadonlyArray s, it tells us we're not meant to change the contents at all, and when we see a function that consumes ReadonlyArray s, it tells us that we can pass any array into that function without worrying that it will change its contents.

Unlike Array, there isn't a ReadonlyArray constructor that we can use.

<div class='code-container'> <code> <div class='line'> new new <data-err> <data-lsp lsp='any'> ReadonlyArray </data-lsp> </data-err> (, , </div> 'ReadonlyArray' only refers to a type, but is being used as a value here. 'ReadonlyArray' only refers to a type, but is being used as a value here. </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwDYCcBmAUAHaQDuoASp, </div>

Instead, we can assign regular Array s to ReadonlyArray s.

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #00000FF"> const </span> <span style="color: #000000"> </span> <span style="color: #0070C1"> <data-lsp lsp='const roArray: readonly string[]' > roArray </data-lsp > </span> <span style="color: #000000">: </span> <span style="color: #000000">: </span> <span style="color: #267F99"> <data-lsp lsp='interface ReadonlyArray&amp;lt;T>' > ReadonlyArray </data-lsp> </span> <span style="color: #000000"> &lt; </span> <span style="color: #267F99"> string </span> <span style="color: #000000"> &gt; = [</span> <span style="color: #31515"> "red" </span> <span style="color: #000000">, </span> </span <span style="color: #000000">, </span> </span> </span <span style="color: #000000">, </span> </span> </span> </span <span style="color: #000000">, </span> </s
```

Just as TypeScript provides a shorthand syntax for Array<Type> with Type[], it also provides a shorthand syntax for ReadonlyArray<Type> with readonly Type[].

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
doStuff(values: readonly string[]): void' >doStuff</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) values: readonly
string[]' >values</data-lsp></span><span style="color: #000000">: </span><span style="color:
#0000FF">readonly</span><span style="color: #000000"> </span><span style="color:
#267F99">string</span><span style="color: #000000">[]) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #008000">// We can read from
'values'...</span></div><div class='line'><span style="color: #000000"> </span>
<span style="color: #0000FF">const</span><span style="color: #000000"> </span><span</pre>
style="color: #0070C1"> < data-lsp lsp='const copy: string[]' > copy < /data-lsp > </span> < span
style="color: #000000"> = </span><span style="color: #001080"> < data-lsp lsp='(parameter)
values: readonly string[]' >values</data-lsp></span><span style="color: #000000">.</span>
<span style="color: #795E26"> <data-lsp lsp='(method) ReadonlyArray&amp;lt;string>.slice(start?:
number | undefined, end?: number | undefined): string[]' >slice < /data-lsp > </span > <span
style="color: #000000">();</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-lsp>
</span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #A31515">`The first value is </span><span style="color:
#0000FF">${</span><span style="color: #001080"><data-lsp lsp='(parameter) values: readonly
string[]' >values</data-lsp></span><span style="color: #000000FF">[</span><span
style="color: #098658">0</span><span style="color: #000000FF">]</span><span style="color:
#0000FF">}</span><span style="color: #A31515">`</span><span style="color: #000000">);
</span></div> <div class='line'><span style="color: #000000"> </span><span style="color:
#008000">// ...but we can't mutate 'values'.</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp</pre>
lsp='(parameter) values: readonly string[]' >values</data-lsp></span><span style="color:</pre>
#000000">.</span><span style="color: #795E26"><data-err><data-lsp lsp='any' >push</data-
lsp></data-err></span><span style="color: #000000">(</span><span style="color:
#A31515"> "hello!" </span> < span style = "color: #000000">); </span> </div> < span class = "error">
<span>Property 'push' does not exist on type 'readonly string[]'.</span><span</pre>
class="code">2339</span></span><span class="error-behind">Property 'push' does not exist on
type 'readonly string[]'.</span><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQAzAVwDsBjAFw
</div>
```

One last thing to note is that unlike the readonly property modifier, assignability isn't bidirectional between regular Array s and ReadonlyArray s.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span > < span
style="color: #000000"> </span> < span style="color: #001080"> < data-lsp lsp='let x: readonly
string[]' >x</data-lsp></span><span style="color: #000000">: </span><span style="color:
#0000FF">readonly</span><span style="color: #000000"> </span><span style="color:
#267F99">string</span><span style="color: #000000">[] = [];</span></div><div class='line'>
<span style="color: #0000FF">let</span><span style="color: #000000"> </span><span</pre>
style="color: #001080"> < data-lsp lsp='let y: string[]' > y < /data-lsp> < /span> < span style="color:
#000000">: </span> <span style="color: #267F99"> string </span> < span style="color: #000000">
[] = [];</span></div> <div class='line'><span style="color: #001080"><data-lsp lsp='let x:
readonly string[]' >x</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #001080"> < data-lsp lsp='let y: string[]' > y < /data-lsp> < /span> < span style="color:
#000000">;</span></div><div class='line'><span style="color: #001080"><data-err><data-lsp
lsp='let y: string[]' >y</data-lsp></data-err></span><span style="color: #000000"> = </span>
<span style="color: #001080"> <data-lsp lsp='let x: readonly string[]' >x</data-lsp> </span>
<span style="color: #000000">;</span></div><span class="error"><span>The type 'readonly
string[]' is 'readonly' and cannot be assigned to the mutable type 'string[]'.</span><span
class="code">4104</span></span><span class="error-behind">The type 'readonly string[]' is
'readonly' and cannot be assigned to the mutable type 'string[]'.</span></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygCwEYAMaBQAbSAF1AA9VplI
</div>
```

Tuple Types

A *tuple type* is another sort of Array type that knows exactly how many elements it contains, and exactly which types it contains at specific positions.

```
 <div
class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> type </span>
  <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='type
  StringNumberPair = [string, number]' > StringNumberPair </data-lsp> </span> <span style="color: #000000"> = [</span> <span style="color: #267F99"> string</span> <span style="color: #000000">, </span> <span style="color: #267F99"> number </span> <span style="color: #000000">, </span> </div> </code> <a class='playground-link'
  href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAysBOBLAdgcwHIFcC2AjC8ACglaLxQC8U
  </div>
```

Here, StringNumberPair is a tuple type of string and number. Like ReadonlyArray, it has no representation at runtime, but is significant to TypeScript. To the type system, StringNumberPair

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
doSomething(pair: [string, number]): void' >doSomething</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) pair: [string,
number]' >pair </data-lsp> </span> < span style="color: #000000">: [</span> < span style="color: #000000">: [</span style="color: #00000
#267F99">string</span><span style="color: #000000">, </span><span style="color:

class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAEzgZTgWwKZQBYxgDmAFAA4C
</div>
```

If we try to index past the number of elements, we'll get an error.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < span style="color: #000000"> < span style="color: #795E26"> < data-lsp lsp='function doSomething(pair: [string, number]): void' > doSomething</data-lsp> < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) pair: [string, number]' > pair < /data-lsp> < span style="color: #000000">: [< span style="color: #267F99"> string < span style="color: #000000">, < span style="color: #267F99"> number < span style="color: #000000">]) { < /div> < div class='line'> < /div> < div class='line'>

 // ... </div> <div class='line'> const const <data-lsp lsp='const c: undefined' > c </data-lsp > = = [<data-err> 2 </data-err>]; </div> Tuple type '[string, number]' of length '2' has no element at index '2'. 2493 < Tuple type '[string, number]' of length '2' has no element at index '2'. <div class='line'> } </div> </code> <a class='playground-link'</pre>

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwBYCcBmAUAGYCuAdgMY/</div>

We can also <u>destructure tuples</u> using JavaScript's array destructuring.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> doSomething(stringHash: [string, number]): void' >doSomething</data-lsp>(<data-lsp lsp='(parameter) stringHash: [string, number]' > stringHash < /data-lsp > < span style="color: #000000">: [string, number]) {</div> <div class='line'> <span style="color:</pre> #0000FF">const [<data-lsp lsp='const inputString: string' >inputString</data-lsp><span style="color:</pre> #000000">, < data-lsp lsp='const hash: number' >hash</data-lsp>] = < data-lsp lsp='(parameter) stringHash: [string, number]' > stringHash < /data-lsp> ;</div> <div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span> (<data-lsp lsp='const</pre> inputString: string' style='border-bottom: solid 2px lightgrey;'>inputString</data-lsp>);</div> <span</pre> class='popover'> < div class='arrow'> </div> const inputString: string < div class='line'> <data-lsp lsp='var</pre> console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp lsp='const hash: number' style='border-bottom: solid 2px lightgrey;'>hash</data-lsp>);</div> <span</pre>

class='popover'> < div class='arrow'> </div> const hash: number < div class='line'> < span style="color: #000000">} </div> </code> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAEzgZTgWwKZQBYxgDmAFAM50 </div>

Tuple types are useful in heavily convention-based APIs, where each element's meaning is "obvious". This gives us flexibility in whatever we want to name our variables when we destructure them. In the above example, we were able to name elements 0 and 1 to whatever we wanted.

However, since not every user holds the same view of what's obvious, it may be worth reconsidering whether using objects with descriptive property names may be better for your API.

Other than those length checks, simple tuple types like these are equivalent to types which are versions of Array s that declare properties for specific indexes, and that declare length with a numeric literal type.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span> <data-lsp lsp='interface</pre> StringNumberPair' > StringNumberPair < /data-lsp > < span style="color: #000000" > {</div><div class='line'> // specialized properties</div><div class='line'> <data-lsp lsp='(property) StringNumberPair.length: 2' >length</data-lsp>: 2;</div><div</pre> class='line'> 0 : string<span</pre> style="color: #000000">;</div><div class='line'> 1: number;</div> <div class='line'> < span style="color: #000000"> < span style="color: #008000"> // Other 'Array<string | number>' members...</div><div class='line'> < data-lsp lsp='(method) StringNumberPair.slice(start?: number | undefined, end?: number | undefined): Array<string | number>' >slice</data-lsp>(< data-lsp lsp='(parameter) start: number | undefined' > start < /data-lsp > < /span > < span style="color: #000000">?: number, <data-lsp lsp='(parameter) end: number | undefined' >end</data-lsp>?: number): < data-lsp lsp='interface Array&lt;T>' > Array < /data-lsp> < /span> <string<span</pre> style="color: #000000"> | number<span

```

Another thing you may be interested in is that tuples can have optional properties by writing out a question mark (? after an element's type). Optional tuple elements can only come at the end, and also affect the type of length.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAysBOBLAdgcwHIFcC2AjC8AQgPbEA2EAl
</div>
```

- StringNumberBooleans describes a tuple whose first two elements are string and number respectively, but which may have any number of boolean's following.
- StringBooleansNumber describes a tuple whose first element is string and then any number of booleans and ending with a number.
- BooleansStringNumber describes a tuple whose starting elements any number of boolean's and ending with a string then a number.

A tuple with a rest element has no set "length" - it only has a set of well-known elements in different positions.

```
 < div</pre>

OkgA'>Try</a></div>
```

Why might optional and rest elements be useful? Well, it allows TypeScript to correspond tuples with parameter lists. Tuples types can be used in <u>rest parameters and arguments</u>, so that the following:

```
#000000">[]]) {</span></div><div class='line'><span style="color: #000000"> </span><span style="color: #00000FF">const</span><span style="color: #000000"> [</span><span style="color: #0070C1"> <data-lsp lsp='const name: string'> name</data-lsp></span><span style="color: #0070C1"> <data-lsp lsp='const version: number' >version</data-lsp></span><span style="color: #000000">, ...</span><span style="color: #000000">, ...</span><span style="color: #0070C1"> <data-lsp></span><span style="color: #0070C1"> <data-lsp lsp='const input: boolean[]'>input</data-lsp></span><span style="color: #000000"> [yarameter) args: [string, number, ...boolean[]]'> args</data-lsp></span><span style="color: #000000">;</span></div><div class='line'> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> </div> <div class='line'> <span style="color: #000000"> </span> </div> </div> </div> <div class='line'> <span style="color: #000000"> </span> </div> </div> </div> </div> <div class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAJwKYEMAmAhEUolCSYADngBC </div>
```

is basically equivalent to:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> readButtonInput(name: string, version: number, ...input: boolean[]): void' > readButtonInput < /datalsp>(<data-lsp lsp='(parameter) name: string' >name</data-lsp> : string, <data-lsp lsp='(parameter) version: number' > version < /data-lsp> : number , ... < data-lsp</pre> lsp='(parameter) input: boolean[]' >input</data-lsp>: boolean[]) {</div><div class='line'> // ...</div><div class='line'>}</div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAJwKYEMAmAhEUolCSYADngBR </div>

This is handy when you want to take a variable number of arguments with a rest parameter, and you need a minimum number of elements, but you don't want to introduce intermediate variables.

<!-- TODO do we need this example? For example, imagine we need to write a function that adds up `number`s based on arguments that get passed in. ```ts twoslash function sum(...args: number[]) { // ... } ``` We might feel like it makes little sense to take any fewer than 2 elements, so we want to require callers to provide at least 2 arguments. A first attempt might be ```ts twoslash function foo(a: number, b: number, ...args: number[]) { args.unshift(a, b); let result = 0; for (const value of args) { result += value; } return result; } ``` -->

readonly Tuple Types

One final note about tuple types - tuples types have readonly variants, and can be specified by sticking a readonly modifier in front of them - just like with array shorthand syntax.

<div class='code-container'> <code> <div class='line'> function <data-lsp lsp='function doSomething(pair: readonly [string, number]): void' >doSomething </data-lsp > (<data-lsp lsp='(parameter) pair: readonly [string, number]' > pair </data-lsp> : [[, string ,]) { </div> <div <la> <div <div class='line'> // ... </div> </div> <div <lass='line'> // ... </div> </div> </div> <div class='line'> // ... </div> </div> </div> </div> </div> <div class='line'> // ... </div> </div> </div> </div> </div> </div> </div> <div class='line'> // ... </div> </div>

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAEzgZTgWwKZQBYxgDmAFAA4C </div>

As you might expect, writing to any property of a readonly tuple isn't allowed in TypeScript.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> doSomething(pair: readonly [string, number]): void' > doSomething < /data-lsp > (< data-lsp lsp='(parameter) pair: readonly [string, number]' >pair</data-lsp>: readonly [<span</pre> style="color: #267F99">string, number]) {</div><div class='line'> < span style="color: #000000"> < span style="color: #001080"> < data-lsp lsp='(parameter) pair: readonly [string, number]' >pair</data-lsp><span style="color:</pre> #000000">[<data-err>0</data-err>] = "hello!";</div>Cannot assign to '0' because it is a read-only property.2540Cannot assign to '0' because it is a read-only property.<div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYAsAGAUAGYCuAdgMYA </div>

Tuples tend to be created and left un-modified in most code, so annotating types as readonly tuples when possible is a good default. This is also important given that array literals with const

assertions will be inferred with readonly tuple types.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span > < span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='let point: readonly

<data-lsp lsp='var Math: Math' > Math/data-lsp></span><span style="color: #000000">.
</span><span style="color: #795E26"><data-lsp lsp='(method) Math.sqrt(x: number): number'
>sqrt</data-lsp></span><span style="color: #000000">(</span><span style="color: #001080">
<data-lsp lsp='var x: number' >x</data-lsp></span><span style="color: #000000"> ** </span>
<span style="color: #098658">2</span><span style="color: #000000"> + </span><span</pre>
style="color: #001080"> < data-lsp lsp='var y: number' > y < /data-lsp> </span> < span style="color:
#000000"> ** </span> <span style="color: #098658">2 </span> <span style="color: #000000">);
</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'> < span style="color: #795E26"> < data-lsp lsp='function distanceFromOrigin([x, y]:
[number, number]): number' > distanceFromOrigin < /data-lsp > </span > < span style="color:
#000000">(</span><span style="color: #001080"> <data-err> <data-lsp lsp='let point: readonly
[3, 4]' >point</data-lsp></data-err></span><span style="color: #000000">);</span></div>
<span class="error"> <span>Argument of type 'readonly [3, 4]' is not assignable to parameter of
type '[number, number]'. The type 'readonly [3, 4]' is 'readonly' and cannot be assigned to the
mutable type '[number, number]'.</span><span class="code">2345</span></span><span
class="error-behind">Argument of type 'readonly [3, 4]' is not assignable to parameter of type
'[number, number]'. The type 'readonly [3, 4]' is 'readonly' and cannot be assigned to the mutable
type '[number, number]'.</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUADaQAuoADn
</div>
```

Here, distanceFromOrigin never modifies its elements, but expects a mutable tuple. Since point 's type was inferred as readonly [3, 4], it won't be compatible with [number,

number] since that type can't guarantee point 's elements won't be mutated.

<!-- ## Other Kinds of Object Members Most of the declarations in object types: ### Method Syntax ### Call Signatures ### Construct Signatures ### Index Signatures -->

Creating Types from Types

TypeScript's type system is very powerful because it allows expressing types *in terms of other types*.

The simplest form of this idea is generics, we actually have a wide variety of *type operators* available to us. It's also possible to express types in terms of *values* that we already have.

By combining various type operators, we can express complex operations and values in a succinct, maintainable way. In this section we'll cover ways to express a new type in terms of an existing type or value.

- Generics Types which take parameters
- <u>Keyof Type Operator</u> Using the keyof operator to create new types
- <u>Typeof Type Operator</u> Using the <u>typeof</u> operator to create new types
- <u>Indexed Access Types</u> Using Type['a'] syntax to access a subset of a type
- Conditional Types Types which act like if statements in the type system
- <u>Mapped Types</u> Creating types by mapping each property in an existing type
- <u>Template Literal Types</u> Mapped types which change properties via template literal strings

Generics

A major part of software engineering is building components that not only have well-defined and consistent APIs, but are also reusable. Components that are capable of working on the data of today as well as the data of tomorrow will give you the most flexible capabilities for building up large software systems.

In languages like C# and Java, one of the main tools in the toolbox for creating reusable components is *generics*, that is, being able to create a component that can work over a variety of types rather than a single one. This allows users to consume these components and use their own types.

Hello World of Generics

To start off, let's do the "hello world" of generics: the identity function. The identity function is a function that will return back whatever is passed in. You can think of this in a similar way to the echo command.

Without generics, we would either have to give the identity function a specific type:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> function </span> <span style="color: #000000"> </span> <span style="color: #795E26"> <data-lsp lsp='function identity(arg: number): number' > identity </data-lsp> </span> <span style="color: #000000"> (</span> <span style="color: #001080"> <data-lsp lsp='(parameter) arg: number' >arg </data-lsp> </span> <span style="color: #000000">: </span> <span style="color: #267F99"> number </span> <span style="color: #000000"> (</span> <span style="color: #267F99"> number </span> <span style="color: #000000"> (</span> </div> <div class='line'> <span style="color: #000000"> </span> <</span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <</span> <span style="color: #000000"> </span> </span> <</span> </div> </div>
```

Or, we could describe the identity function using the any type:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </span> < span style="color: #000000"> </span> < span style="color: #795E26"> < data-lsp lsp='function identity(arg: any): any' > identity < / data-lsp> < / span> < span style="color: #000000"> (< / span>
```

```
<span style="color: #001080"> <data-lsp lsp='(parameter) arg: any' >arg</data-lsp> </span>
<span style="color: #000000">: </span> <span style="color: #267F99"> any </span> <span style="color: #000000">): </span> <span style="color: #267F99"> any </span> <span style="color: #000000"> (span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) arg: any' >arg </data-lsp> </span> <span style="color: #000000">;</span> </div> <div class='line'> <span style="color: #000000">} </span> </div> </div> <div class='line'> <span style="color: #000000">} </span> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAFAQwCcBzALkXzGv </div>
```

While using any is certainly generic in that it will cause the function to accept any and all types for the type of arg, we actually are losing the information about what that type was when the function returns. If we passed in a number, the only information we have is that any type could be returned.

Instead, we need a way of capturing the type of the argument in such a way that we can also use it to denote what is being returned. Here, we will use a *type variable*, a special kind of variable that works on types rather than values.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
identity<Type>(arg: Type): Type' >identity</data-lsp></span><span style="color:
#000000"><</span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in
identity<Type>(arg: Type): Type' > Type</data-lsp> </span> < span style="color:
#000000">>(</span><span style="color: #001080"><data-lsp lsp='(parameter) arg: Type'
>arg</data-lsp></span><span style="color: #000000">: </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Type in identity&amp;lt;Type>(arg: Type): Type' > Type</data-lsp>
</span><span style="color: #000000">): </span><span style="color: #267F99"> < data-lsp
lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp></span>
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #AF00DB">return</span><span style="color: #000000"> </span>
<span style="color: #001080"> <data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > </span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAPAFWwAc0A+ACg
</div>
```

We've now added a type variable Type to the identity function. This Type allows us to capture the type the user provides (e.g. number), so that we can use that information later. Here, we use Type again as the return type. On inspection, we can now see the same type is used for the argument and the return type. This allows us to traffic that type information in one side of the function and out the other.

We say that this version of the identity function is generic, as it works over a range of types.

Unlike using any, it's also just as precise (ie, it doesn't lose any information) as the first identity function that used numbers for the argument and return type.

Once we've written the generic identity function, we can call it in one of two ways. The first way is to pass all of the arguments, including the type argument, to the function:

<div class='code-container'> <code> <div class='line'> let let <data-lsp lsp='let output: string' style='border-bottom: solid 2px lightgrey;'> output </data-lsp> = <data-lsp lsp='function identity&lt;string> (arg: string): string' > identity </data-lsp> < string >("myString"); </div> <div class='arrow'> </div> let output: string </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAPAFWwAc0A+ACg </div>

Here we explicitly set Type to be string as one of the arguments to the function call, denoted using the <> around the arguments rather than ().

The second way is also perhaps the most common. Here we use *type argument inference* -- that is, we want the compiler to set the value of Type for us automatically based on the type of the argument we pass in:

<div class='code-container'> <code> <div class='line'> let let <data-lsp lsp='let output: string' style='border-bottom: solid 2px lightgrey;'> output </data-lsp> = <data-lsp lsp='function identity&lt;&quot;myString&quot;> (arg: &quot;myString&quot;): &quot;myString&quot;' > identity </data-lsp> (); </div> <div class='arrow'> </div> let output: string </code> Try </div> </div>

Notice that we didn't have to explicitly pass the type in the angle brackets (<>); the compiler just looked at the value "myString", and set Type to its type. While type argument inference can be a helpful tool to keep code shorter and more readable, you may need to explicitly pass in the type

arguments as we did in the previous example when the compiler fails to infer the type, as may happen in more complex examples.

Working with Generic Type Variables

When you begin to use generics, you'll notice that when you create generic functions like identity, the compiler will enforce that you use any generically typed parameters in the body of the function correctly. That is, that you actually treat these parameters as if they could be any and all types.

Let's take our identity function from earlier:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
identity<Type>(arg: Type): Type' >identity</data-lsp></span><span style="color:
#000000"><</span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in
identity<Type>(arg: Type): Type' >Type</data-lsp></span><span style="color:
#000000">>(</span><span style="color: #001080"><data-lsp lsp='(parameter) arg: Type'
>arg</data-lsp></span><span style="color: #000000">: </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Type in identity&amp;lt;Type>(arg: Type): Type' > Type</data-lsp>
</span><span style="color: #000000">): </span><span style="color: #267F99"> < data-lsp
lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp></span>
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #AF00DB">return</span><span style="color: #000000"> </span>
<span style="color: #001080"> <data-lsp lsp='(parameter) arg: Type' > arg </data-lsp> </span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAPAFWwAc0A+ACg
</div>
```

What if we want to also log the length of the argument arg to the console with each call? We might be tempted to write this:

class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </ span>
 < span style="color: #000000"> </ span> < span style="color: #795E26"> < data-lsp lsp='function
loggingldentity&lt;Type> (arg: Type): Type' > loggingldentity < / data-lsp > </ span> < span
style="color: #000000"> & lt; < / span> < span style="color: #267F99"> < data-lsp lsp='(type
parameter) Type in loggingldentity&lt;Type> (arg: Type): Type' > Type < / data-lsp < </ span>
 < span style="color: #000000"> & gt;(</ span> < span style="color: #001080"> < data-lsp
lsp='(parameter) arg: Type' > arg < / data-lsp < < span style="color: #000000">: < / span>
 < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in</pre>

loggingIdentity<Type>(arg: Type): Type' >Type</data-lsp>): < data-lsp lsp='(type parameter) Type in loggingIdentity<Type>(arg: Type): Type' >Type</data-lsp> { </div> <div class='line'> < data-lsp lsp='var console: Console' > console < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(<data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > .<data-err><data-lsp</pre> lsp='any' >length</data-lsp></data-err>); </div>Property 'length' does not exist on type 'Type'.2339Property 'length' does not exist on type 'Type'.<div class='line'> return < data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > < span style="color: #000000">;</div><div class='line'>} </div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQAzAVwDsBjAFw </div>

When we do, the compiler will give us an error that we're using the .length member of arg, but nowhere have we said that arg has this member. Remember, we said earlier that these type variables stand in for any and all types, so someone using this function could have passed in a number instead, which does not have a .length member.

Let's say that we've actually intended this function to work on arrays of Type rather than Type directly. Since we're working with arrays, the .length member should be available. We can describe this just like we would create arrays of other types:

<div class='code-container'> <code> <div class='line dim'> <data-lsp lsp='function loggingldentity&lt;Type> (arg: Type[]): Type[]' >loggingldentity </data-lsp > < <data-lsp lsp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp> <data-lsp lsp='(parameter) arg: Type[]' >arg </data-lsp> : <data-lsp lsp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type[]): Type[]' >Type</data-lsp |sp='(type parameter) Type |span> (span> (s

```
>console</data-lsp></span><span style="color: #000000">.</span><span style="color: #795E26"> <data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><<span style="color: #000000">(</span> <span style="color: #001080"> <data-lsp lsp='(parameter) arg: Type[]' >arg</data-lsp> </span> <span style="color: #000000">.</span> <span style="color: #000000">.</span> <span style="color: #000000">.</span> <span style="color: #000000">);</span> </div> <div class='line dim'> <span style="color: #000000"> </span> <span style="color: #AF00DB"> return </span> <span style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) arg: Type[]' >arg</data-lsp> </span> <span style="color: #000000">;</span> </div> <div class='line dim'> <span style="color: #000000">;</span> </div> </div>
```

You can read the type of loggingIdentity as "the generic function loggingIdentity takes a type parameter Type, and an argument arg which is an array of Type s, and returns an array of Type s." If we passed in an array of numbers, we'd get an array of numbers back out, as Type would bind to number. This allows us to use our generic type variable Type as part of the types we're working with, rather than the whole type, giving us greater flexibility.

We can alternatively write the sample example this way:

```
 < div</pre>
class='code-container'> < code> < div class='line dim'> < span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function loggingIdentity&amp;lt;Type>(arg: Array&amp;lt;Type>):
Array<Type>' >loggingIdentity</data-lsp></span><span style="color: #000000">&lt;
</span> < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in
loggingIdentity&It;Type>(arg: Type[]): Type[]' > Type</data-lsp> </span> < span style="color:
#000000">>(</span><span style="color: #001080"><data-lsp lsp='(parameter) arg: Type[]'
>arg</data-lsp></span><span style="color: #000000">: </span><span style="color: #267F99">
<data-lsp lsp='interface Array&amp;lt;T>' >Array</data-lsp></span><span style="color:
#000000"><</span><span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in
loggingIdentity&It;Type>(arg: Type[]): Type[]' > Type</data-lsp> </span> < span style="color:
#000000">>): </span> <span style="color: #267F99"> <data-lsp lsp='interface
Array<T>' >Array</data-lsp></span><span style="color: #000000">&lt;</span><span
style="color: #267F99"> < data-lsp lsp='(type parameter) Type in loggingIdentity&amp;lt;Type>
(arg: Type[]): Type[]' > Type < /data-lsp > </span > < span style = "color: #000000" > & gt; { </span >
</div><div class='line highlight'><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span> < span style="color:
#000000">.</span><span style="color: #795E26"><data-lsp lsp='(method) Console.log(...data:
any[]): void' >log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) arg: Type[]' > arg < /data-lsp > </span > < span style="color:
```

```
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property)

Array&amp;lt;Type>.length: number' >length</data-lsp></span><span style="color: #000000">);

</span><span style="color: #008000">// Array has a .length, so no more error</span></div>

<div class='line dim'><span style="color: #000000"> </span><span style="color:

#AF00DB">return</span><span style="color: #000000"> </span><span style="color:

#001080"> <data-lsp lsp='(parameter) arg: Type[]' >arg</data-lsp></span><span style="color:

#000000">;</span></div><div class='line dim'> <span style="color: #000000">}</span></div>

</code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABAGzgczTMaCSATAUzFigE8AeAFV
</div>
```

You may already be familiar with this style of type from other languages. In the next section, we'll cover how you can create your own generic types like Array<Type>.

Generic Types

In previous sections, we created generic identity functions that worked over a range of types. In this section, we'll explore the type of the functions themselves and how to create generic interfaces.

The type of generic functions is just like those of non-generic functions, with the type parameters listed first, similarly to function declarations:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> identity<Type>(arg: Type): Type' >identity</data-lsp>< <data-lsp lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp>>(<data-lsp lsp='(parameter) arg: Type' >arg</data-lsp>: <data-lsp lsp='(type parameter) Type in identity&lt;Type>(arg: Type): Type' > Type</data-lsp>): < data-lsp lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp> {</div><div class='line'> return <data-lsp lsp='(parameter) arg: Type' > arg </data-lsp> ;</div><div class='line'>} </div> <div class='line'> let <data-lsp lsp='let myldentity: &lt;Type> (arg: Type) => Type' >myldentity</data-lsp>: < < data-lsp lsp='(type parameter) Type in & amp;lt;Type>(arg: Type): Type' >Type</data-lsp>&qt;(< data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > < span style="color:

#000000">: <data-lsp lsp='(type parameter) Type in &lt;Type>(arg: Type): Type' >Type</data-lsp>) = > <data-lsp lsp='(type parameter) Type in &lt;Type>(arg: Type): Type' >Type</data-lsp> = <data-lsp lsp='function identity&lt;Type>(arg: Type): Type' >identity </data-lsp> ; </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAPAFWwAc0A+ACg </div>

We could also have used a different name for the generic type parameter in the type, so long as the number of type variables and how the type variables are used line up.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function</pre> identity<Type>(arg: Type): Type' >identity</data-lsp>< < data-lsp lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp>>(<data-lsp lsp='(parameter) arg: Type' >arg</data-lsp>: <data-lsp lsp='(type parameter) Type in identity&lt;Type>(arg: Type): Type' >Type</data-lsp>): < data-lsp lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp> {</div><div class='line'> return <data-lsp lsp='(parameter) arg: Type' >arg</data-lsp> ;</div><div class='line'>} </div> <div class='line'>let <data-lsp lsp='let myldentity: &lt;lnput> (arg: Input) => Input' >myldentity</data-lsp>: < <data-lsp lsp='(type parameter) Input in & amp;lt;Input> (arg: Input): Input' > Input < /data-lsp > < span style="color: #000000" > & gt; (< /span > < span style="color: #001080"> < data-lsp lsp='(parameter) arg: Input' > arg < /data-lsp > < span style="color: #000000">: < span style="color: #267F99"> < data-lsp lsp='(type parameter) Input in & amp;It;Input>(arg: Input): Input' > Input < /data-lsp> < /span> < span style="color: #000000">) = &qt; <data-lsp lsp='(type parameter) Input in & amp;lt;Input> (arg: Input): Input' > Input < /data-lsp > = < data-lsp lsp='function identity&lt;Type> (arg: Type): Type' >identity</data-lsp>;</div></code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAPAFWwAc0A+ACg </div>

We can also write the generic type as a call signature of an object literal type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>

</span><span style="color: #001080"><data-lsp lsp='function identity&amp;lt;Type>(arg: Type):
Type' >identity</data-lsp></span><span style="color: #000000">;</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABDAJgUzLKBPAPAFWwAc0A+ACg
</div>
```

Which leads us to writing our first generic interface. Let's take the object literal from the previous example and move it to an interface:

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface
 < span style="color: #000000"> < span style="color: #267F99"> < data-lsp lsp='interface
GenericIdentityFn' > GenericIdentityFn < / data-lsp> < / span> < span style="color: #000000">
{ < / div > < div class='line'> < span style="color: #000000"> & lt; < / span> < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in & amp;lt;Type> (arg: Type): Type' > Type < / data-lsp < / span> < span style="color: #001080"> < data-lsp | sp='(parameter) arg: Type' > arg < / data-lsp> < / span> < span style="color: #000000"> : < / span></ span> < span style="color: #000000"> : < / span > style="color: #000000"> : < span style="color: #00000

```
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in & amp;lt;Type>(arg: Type):
Type' >Type</data-lsp></span><span style="color: #000000">): </span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Type in & amp;lt;Type> (arg: Type): Type' > Type < /data-
lsp></span><span style="color: #000000">;</span></div><div class='line'><span style="color:
#000000">}</span></div> <div class='line'><span style="color: #0000FF">function</span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
identity<Type>(arg: Type): Type' >identity</data-lsp></span><span style="color:
#000000"><</span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in
identity<Type>(arg: Type): Type' >Type</data-lsp></span><span style="color:
#000000">>(</span><span style="color: #001080"><data-lsp lsp='(parameter) arg: Type'
>arg</data-lsp></span><span style="color: #000000">: </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Type in identity&amp;lt;Type>(arg: Type): Type' > Type</data-lsp>
</span><span style="color: #000000">): </span><span style="color: #267F99"> < data-lsp
lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp></span>
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #AF00DB">return</span><span style="color: #000000"> </span>
<span style="color: #001080"> <data-lsp lsp='(parameter) arg: Type' > arg </data-lsp> </span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div> <div class='line'><span style="color: #0000FF">let</span><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='let myldentity:
GenericIdentityFn' >myldentity</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='interface GenericIdentityFn'</pre>
>GenericIdentityFn</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #001080"> < data-lsp lsp='function identity&amp;lt;Type> (arg: Type): Type'
>identity</data-lsp></span><span style="color: #000000">;</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgOIRNYCCSATDMYMATwDERI
</div>
```

In a similar example, we may want to move the generic parameter to be a parameter of the whole interface. This lets us see what type(s) we're generic over (e.g. Dictionary<string> rather than just Dictionary). This makes the type parameter visible to all the other members of the interface.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < span style="color: #000000"> < span style="color: #267F99"> < data-lsp lsp='interface GenericIdentityFn&lt;Type>' > GenericIdentityFn</data-lsp> < span style="color: #000000"> < < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in GenericIdentityFn&lt;Type>' > Type</data-lsp> < span style="color: #000000"> > </div> < div class='line'> < span style="color: #000000"> (< span style="color: #001080"> < data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp lsp='(type parameter) Type in GenericIdentityFn&lt;Type>' > Type</data-lsp> < span style="color: #000000">):

 <data-lsp lsp='(type parameter) Type in GenericIdentityFn<Type>' >Type</data-lsp>; </div><div class='line'>}</div> <div class='line'>function <data-lsp lsp='function identity&lt;Type>(arg: Type): Type' >identity</data-lsp>< < data-lsp lsp='(type parameter) Type in identity&lt;Type>(arg: Type): Type' >Type</data-lsp>&qt;(<data-lsp lsp='(parameter) arg: Type' > arg </data-lsp> : <data-lsp lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp>): < data-lsp lsp='(type parameter) Type in identity<Type>(arg: Type): Type' >Type</data-lsp> {</div><div class='line'> return < data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > < span style="color: #000000">;</div><div class='line'>}</div> <div class='line'> < span style="color: #0000FF">let < / span> < span style="color: #000000"> < / span> < data-lsp lsp='let myldentity: GenericIdentityFn&lt;number>' >myldentity</data-lsp>: < data-lsp lsp='interface GenericIdentityFn&lt;Type>' > GenericIdentityFn < /datalsp><number> = < data-lsp lsp='function identity&lt;Type>(arg: Type): Type' > identity < /data-lsp> ;</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgOIRNYCCSATDMYMATwDEQ. </div>

Notice that our example has changed to be something slightly different. Instead of describing a generic function, we now have a non-generic function signature that is a part of a generic type. When we use <code>GenericIdentityFn</code>, we now will also need to specify the corresponding type argument (here: number), effectively locking in what the underlying call signature will use. Understanding when to put the type parameter directly on the call signature and when to put it on the interface itself will be helpful in describing what aspects of a type are generic.

In addition to generic interfaces, we can also create generic classes. Note that it is not possible to create generic enums and namespaces.

Generic Classes

A generic class has a similar shape to a generic interface. Generic classes have a generic type parameter list in angle brackets (<>) following the name of the class.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
GenericNumber<NumType>' > GenericNumber < /data-lsp> < /span> < span style="color:
#000000"><</span><span style="color: #267F99"><data-lsp lsp='(type parameter) NumType
in GenericNumber<NumType>' > NumType</data-lsp> </span> < span style="color:
#000000">> {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(property) GenericNumber&amp;lt;NumType>.zeroValue:
NumType' >zeroValue</data-lsp></span><span style="color: #000000">: </span><span
style="color: #267F99"> < data-lsp lsp='(type parameter) NumType in
GenericNumber<NumType>' > NumType</data-lsp> </span> < span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #795E26"> < data-lsp lsp='(property) GenericNumber&amp;lt;NumType>.add: (x:
NumType, y: NumType) => NumType' >add</data-lsp></span><span style="color: #000000">:
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) x: NumType' > x < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99"> < data-lsp
lsp='(type parameter) NumType in GenericNumber<NumType>' > NumType</data-lsp>
</span><span style="color: #000000">, </span><span style="color: #001080"> < data-lsp
lsp='(parameter) y: NumType' >y</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='(type parameter) NumType in</pre>
GenericNumber<NumType>' > NumType</data-lsp> </span> < span style="color:
#000000">) </span> <span style="color: #0000FF"> = &qt; </span> <span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='(type parameter) NumType in
GenericNumber<NumType>' > NumType</data-lsp> </span> < span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #0000FF">let</span><span style="color: #000000"> </span>
<span style="color: #001080"> < data-lsp lsp='let myGenericNumber:</pre>
GenericNumber<number>' >myGenericNumber</data-lsp></span><span style="color:
#000000"> = </span><span style="color: #0000FF">new</span><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='constructor
GenericNumber<number>(): GenericNumber&amp;lt;number>' > GenericNumber</data-
lsp></span><span style="color: #000000">&lt;</span><span style="color:
#267F99">number</span><span style="color: #000000">&gt;();</span></div><div
class='line'> < span style="color: #001080"> < data-lsp lsp='let myGenericNumber:
GenericNumber<number>' >myGenericNumber</data-lsp></span><span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property)
GenericNumber<number>.zeroValue: number' >zeroValue</data-lsp></span><span
style="color: #000000"> = </span><span style="color: #098658">0</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #001080"><data-lsp lsp='let
myGenericNumber: GenericNumber<number>' >myGenericNumber</data-lsp></span>
<span style="color: #000000">.</span><span style="color: #795E26"><data-lsp lsp='(property)</pre>
GenericNumber<number>.add: (x: number, y: number) => number' >add</data-lsp>
</span><span style="color: #000000"> = </span><span style="color:
```

```
#0000FF">function</span><span style="color: #000000"> (</span><span style="color: #001080"> <data-lsp lsp='(parameter) x: number' >x</data-lsp ></span><span style="color: #000000">, </span><span style="color: #001080"> <data-lsp lsp='(parameter) y: number' >y</data-lsp></span><span style="color: #000000">) {</span></div><div class='line'> <span style="color: #000000"> </span> <span style="color: #AF00DB"> return</span> <span style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) x: number' >x</data-lsp> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) y: number' >y</data-lsp> </span> <span style="color: #001080"> <data-lsp lsp='(parameter) y: number' >y</data-lsp> </span> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #000000"> };</span> </div> <div class='line'> <span style="color: #000000"> ;</span> </div> </div>
```

This is a pretty literal use of the GenericNumber class, but you may have noticed that nothing is restricting it to only use the number type. We could have instead used string or even more complex objects.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span > < span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='let stringNumeric:
GenericNumber<string>' >stringNumeric</data-lsp></span><span style="color:
#000000"> = </span><span style="color: #0000FF">new</span><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='constructor
GenericNumber<string>(): GenericNumber&amp;lt;string>' > GenericNumber < /data-lsp>
</span><span style="color: #000000">&lt;</span><span style="color: #267F99">string</span>
<span style="color: #000000">&gt;();</span></div><div class='line'><span style="color:</pre>
#001080"> < data-lsp lsp='let stringNumeric: GenericNumber&amp;lt;string>'

#001080"> < data-lsp lsp='(parameter) y: string' > y < /data-lsp > < span style="color: #000000">;</div><div class='line'>};</div> <div class='line'> <data-lsp lsp='var console: Console'</pre> >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span> (<data-lsp lsp='let</pre> stringNumeric: GenericNumber<string>' > stringNumeric</data-lsp> < span style="color: #000000">.<data-lsp lsp='(property) GenericNumber<string>.add: (x: string, y: string) => string' >add</data-lsp>(<data-lsp lsp='let stringNumeric: GenericNumber<string>' > stringNumeric</data-lsp> < span style="color: #000000">.<data-lsp lsp='(property) GenericNumber<string>.zeroValue: string' >zeroValue</data-lsp>, "test" < span style="color: #000000">));</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEGcBcCcEsDG0BcoBmBDANpApgFCLaaSSgDie/ C3yF4AlKAC8YjU50BfAiFAAWmDEJmhqwlJsPGhQGARqAHMeOiR3UFoAd0oaVMZWDlhOePgkkWNnHR </div>

Just as with interface, putting the type parameter on the class itself lets us make sure all of the properties of the class are working with the same type.

As we cover in <u>our section on classes</u>, a class has two sides to its type: the static side and the instance side. Generic classes are only generic over their instance side rather than their static side, so when working with classes, static members can not use the class's type parameter.

Generic Constraints

If you remember from an earlier example, you may sometimes want to write a generic function that works on a set of types where you have *some* knowledge about what capabilities that set of types will have. In our loggingIdentity example, we wanted to be able to access the .length property of arg , but the compiler could not prove that every type had a .length property, so it warns us that we can't make this assumption.

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function </ span> < span style="color: #000000"> </ span> < span style="color: #795E26"> < data-lsp lsp='function loggingldentity&lt;Type> (arg: Type): Type' > loggingldentity < / data-lsp > </ span> < span style="color: #000000"> & lt; </ span> < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in loggingldentity&lt;Type> (arg: Type): Type' > Type < / data-lsp < < span> < span style="color: #000000"> & gt;(</ span> < span style="color: #001080"> < data-lsp lsp='(parameter) arg: Type' > arg < / data-lsp < < span> < span style="color: #000000">: </ span> < < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in</pre>

loggingIdentity<Type>(arg: Type): Type' >Type</data-lsp>): < data-lsp lsp='(type parameter) Type in loggingIdentity<Type>(arg: Type): Type' >Type</data-lsp> { </div> <div class='line'> < data-lsp lsp='var console: Console' > console < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(<data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > .<data-err><data-lsp</pre> lsp='any' >length</data-lsp></data-err>); </div>Property 'length' does not exist on type 'Type'.2339Property 'length' does not exist on type 'Type'.<div class='line'> return < data-lsp lsp='(parameter) arg: Type' > arg < /data-lsp > < span style="color: #000000">;</div><div class='line'>} </div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQAzAVwDsBjAFw </div>

Instead of working with any and all types, we'd like to constrain this function to work with any and all types that *also* have the .length property. As long as the type has this member, we'll allow it, but it's required to have at least this member. To do so, we must list our requirement as a constraint on what Type can be.

To do so, we'll create an interface that describes our constraint. Here, we'll create an interface that has a single .length property and then we'll use this interface and the extends keyword to denote our constraint:

<div class='code-container'> <code> <div class='line'> interface <data-lsp lsp='interface Lengthwise' > Lengthwise </data-lsp> { </div> <div class='line'> <data-lsp lsp='(property) Lengthwise.length: number' > length </data-lsp> : number { </div> <div class='line'> { </div> <div class='line'> { <data-lsp lsp='function loggingldentity&lt;Type extends Lengthwise> (arg: Type): Type' > loggingldentity </data-lsp lsp='(type parameter) Type in loggingldentity&lt;Type extends Lengthwise> (arg: Type): Type' > Type </data-lsp > < <data-lsp lsp='interface</td>

```
Lengthwise' >Lengthwise</data-lsp></span><span style="color: #000000">&qt;(</span><span
style="color: #001080"> < data-lsp lsp='(parameter) arg: Type extends Lengthwise' > arg < /data-
lsp></span><span style="color: #000000">: </span><span style="color: #267F99"> < data-lsp
Isp='(type parameter) Type in loggingIdentity&It;Type extends Lengthwise>(arg: Type): Type'
>Type</data-lsp></span><span style="color: #000000">): </span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Type in loggingIdentity&amp;It;Type extends
Lengthwise>(arg: Type): Type' > Type</data-lsp> </span> < span style="color: #000000">
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span> < span style="color:
\#000000">.</span><span style="color: \#795E26"><data-lsp lsp='(method) Console.log(...data:
any[]): void' >log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) arg: Type extends Lengthwise' > arg < /data-lsp > < /span>
<span style="color: #000000">.</span><span style="color: #001080"><data-lsp lsp='(property)</pre>
Lengthwise.length: number' >length </data-lsp> </span> < span style="color: #000000">); </span>
<span style="color: #008000">// Now we know it has a .length property, so no more error</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(parameter) arg: Type extends Lengthwise' > arg < /data-lsp > < /span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgDIRAczACwO7ADOKA3gFDL
2kKyBJMJxGqA6KhlHZ1CrHHcuZAB6eOQAOXE8ZDwUAGsQNORqMGQcOAs4ZCisXGQ9KHEDKA0AGml
</div>
```

Because the generic function is now constrained, it will no longer work over any and all types:

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAJYB2ALjAGYCzYYpUFoSBJJaH1w5iVVEFAAWibqSRImhrxsoxMLKwJbElwioA'>Try</div>

Instead, we need to pass in values whose type has all the required properties:

```
 < div
class='code-container' > < code > < div class='line' > < span style="color: #795E26" > < data-lsp
lsp='function loggingIdentity&amp;lt;{&amp;#13; length: number;&amp;#13; value:
number;&amp;#13;} > (arg: {&amp;#13; length: number;&amp;#13; value: number;&amp;#13;}):
```

{
 length: number;
 value: number;
}' >loggingldentity </data-lsp ({ <data-lsp lsp='(property) length: number' >length </data-lsp>: , <data-lsp lsp='(property) value: number' >value </data-lsp>: <data-lsp lsp='(property) value: number' >value </data-lsp>: 3 3 }); </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgDIRAczACwO7ADOKA3gFDL 2kKyBJMJxGgA6KhIHZ1CrHHceSigIMGYoKSdMHn4AekzkAFp8hGYwfNyyMNI5ZVVgDXsSamjGAEYABgAa </div>

Using Type Parameters in Generic Constraints

You can declare a type parameter that is constrained by another type parameter. For example, here we'd like to get a property from an object given its name. We'd like to ensure that we're not accidentally grabbing a property that does not exist on the obj, so we'll place a constraint between the two types:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
getProperty&It;Type, Key extends keyof Type>(obj: Type, key: Key): Type[Key]'
>getProperty</data-lsp></span><span style="color: #000000">&lt;</span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Type in getProperty&amp;lt;Type, Key extends keyof
Type>(obj: Type, key: Key): Type[Key]' >Type</data-lsp></span><span style="color: #000000">,
</span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Key in
getProperty<Type, Key extends keyof Type>(obj: Type, key: Key): Type[Key]' > Key</data-
lsp></span><span style="color: #000000"> </span><span style="color:
#0000FF">extends</span><span style="color: #000000"> </span><span style="color:
#0000FF">keyof</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Type in getProperty&amp;lt;Type, Key extends keyof Type>(obj:
Type, key: Key): Type[Key]' >Type</data-lsp></span><span style="color: #000000">&gt;(</span>
<span style="color: #001080"> <data-lsp lsp='(parameter) obj: Type' >obj </data-lsp> </span>
<span style="color: #000000">: </span><span style="color: #267F99"> < data-lsp lsp='(type</pre>
parameter) Type in getProperty&It;Type, Key extends keyof Type>(obj: Type, key: Key):
Type[Key]' >Type</data-lsp></span><span style="color: #000000">, </span><span style="color:

Using Class Types in Generics

When creating factories in TypeScript using generics, it is necessary to refer to class types by their constructor functions. For example,

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
create<Type>(c: {&amp;#13; new (): Type;&amp;#13;}): Type' > create</data-lsp> </span>
<span style="color: #000000">&lt;</span><span style="color: #267F99"><data-lsp lsp='(type</pre>
parameter) Type in create<Type>(c: new () => Type): Type' >Type</data-lsp></span>
<span style="color: #000000">&qt;(</span><span style="color: #001080"><data-lsp</pre>
lsp='(parameter) c: new () => Type' >c</data-lsp></span><span style="color: #000000">: {
</span><span style="color: #0000FF">new</span><span style="color: #000000"> (): </span>
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in create&amp;lt;Type>(c:
new () => Type): Type' >Type</data-lsp></span><span style="color: #000000"> }): </span>
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in create&amp;lt;Type>(c:
new () => Type): Type' >Type</data-lsp></span><span style="color: #000000"> {</span></div>
<div class='line'><span style="color: #000000"> </span><span style="color:</pre>
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#0000FF">new</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='(parameter) c: new () => Type' >c</data-lsp></span><span style="color:</pre>
#000000">();</span></div><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABBATgUwIZTQHgCoCeADmgHwAI
</div>
```

A more advanced example uses the prototype property to infer and constrain relationships between the constructor function and the instance side of class types.

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> class </span> < <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='class BeeKeeper'> BeeKeeper </data-lsp> </span> <span style="color: #000000"> {</span> </div> <div class='line'> <span style="color: #001080"> <data-lsp lsp='(property) BeeKeeper.hasMask: boolean' > hasMask </data-lsp> </span> <span style="color: #000000">: </span> <span style="color: #267F99"> boolean </span> <span style="color: #000000">; </span> <span style="color: #000000">; </span> </div> <div class='line'> <span style="color: #000000"> } </span> </div> <div class='line'> <span style="color: #000000"> } </span> </div> <div class='line'> <span style="color: #000000"> </span> </span> <span style="color: #000000"> </spa
```

```
>nametag</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000"> = </span><span style="color:
#A31515">"Mikle"</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000">}</span></div> <div class='line'><span style="color:</pre>
#0000FF">class</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='class Animal' > Animal </data-lsp> </span> < span style="color: #000000">
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(property) Animal.numLegs: number' > numLegs < /data-lsp > < /span>
<span style="color: #000000">: </span><span style="color: #267F99">number</span><span</pre>
style="color: #000000"> = </span><span style="color: #098658">4</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div> <div

boolean' >hasMask</data-lsp></span><span style="color: #000000">;</span></div></code>
<a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEGcBcCcEsDG0BcoBmBDANpApgFCLaaSSgBCer
iM0F8VndolpYDJ9qBEKNxrd7ngni9LnghlMZiMAHRrExkizWWx2NQ4zCPZ62QlDNrkylMMncSB8SD8FRA
```

This pattern is used to power the mixing design pattern.

</div>

Keyof Type Operator

The keyof type operator

The keyof operator takes an object type and produces a string or numeric literal union of its keys:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type Point</pre> = {
 x: number;
 y: number;
}' >Point</data-lsp> = { < span style="color: #001080"> < data-lsp lsp='(property) x:$ number' >x</data-lsp>: number; < data-lsp lsp='(property) y: number' > y < /data-lsp > < span style="color: #000000">: number number number number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999 };</div><div class='line'>type < data-lsp lsp='type P = keyof Point' style='border-bottom: solid 2px lightgrey;'>P</data-lsp> = keyof <data-lsp lsp='type Point = {&#13; x: number;
 y: number;
}' >Point</data-lsp>;</div> <div class='arrow'></div>type P = keyof Point</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBACg9gSwHbCgXigbygDwFxRICuAtgEYQB </div>

If the type has a string or number index signature, keyof will return those types instead:

<div class='code-container'> <code> <div class='line'> type <data-lsp lsp='type</p>
Arrayish = {&#13; [n: number]: unknown;&#13;}' > Arrayish
/data-lsp > <data-lsp lsp='(parameter) n: number' > n</data-lsp> : number]: unknown }; </div> <div class='line'> type <data-lsp lsp='type A = number' style='border-bottom: solid 2px lightgrey;'> A</data-lsp> <span

```
<data-lsp lsp='type Arrayish = {&amp;#13; [n: number]: unknown;&amp;#13;}' > Arrayish < /data-</pre>
lsp></span><span style="color: #000000">;</span></div><span class='popover-prefix'>
</span><span class='popover'><div class='arrow'></div>type A = number</span> <div
class='line'><span style="color: #0000FF">type</span><span style="color: #000000"> </span>
<span style="color: #267F99"> < data-lsp lsp='type Mapish = {&amp;#13; [k: string]:</pre>
boolean;
}' > Mapish < /data-lsp > </span > <span style="color: #000000" > = { [ </span >
<span style="color: #001080"> < data-lsp lsp='(parameter) k: string' > k < /data-lsp > </span > <span</pre>
style="color: #000000">: </span><span style="color: #267F99">string</span><span
style="color: #000000">]: </span><span style="color: #267F99">boolean</span><span
style="color: #000000"> };</span></div><div class='line'><span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type M = string | number' style='border-bottom: solid 2px lightgrey;'>M</data-lsp>
</span><span style="color: #000000"> = </span><span style="color: #0000FF">keyof</span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Mapish = {
 [k: string]: boolean;
}' > Mapish < /data-lsp > </span > <span
style="color: #000000">;</span></div><span class='popover-prefix'> </span><span
class='popover'> < div class='arrow'> </div>type M = string | number </span> </code> < a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAggTnAhiAlgZwBZQLxQN5QDaAdgFxTEC
MNHhoAWURqVkgoTbk0wOCmIBzZIFqdOAGwiI+Qw+LGktKyCqbmmOqaOrpAA'>Try</a></div>
```

Note that in this example, M is string | number -- this is because JavaScript object keys are always coerced to a string, so obj[0] is always the same as obj["0"].

keyof types become especially useful when combined with mapped types, which we'll learn more about later.

Typeof Type Operator

The type of type operator

JavaScript already has a typeof operator you can use in an expression context:

<div class='code-container'> <code> <div class='line'> // Prints "string" </div> <div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp> . <data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp> (typeof ("Hello world"); </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAUCcEsDsBcDOoBEj41gcxQKAMYD2sihANgKYB0 </div>

TypeScript adds a typeof operator you can use in a *type* context to refer to the *type* of a variable or property:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> let < / span> < span style="color: #00000FF"> let < / span> < span style="color: #001080"> < data-lsp lsp='let s: string' > s < / data-lsp> < / span> < span style="color: #000000"> = < / span> < span style="color: #00000"> ; < / span> < span style="color: #00000"> ; < / span> < / div> < div class='line'> < span style="color: #00000FF"> let < / span> < span style="color: #00000"> < / span> < span style="color: #001080"> < data-lsp lsp='let n: string' style='border-bottom: solid 2px lightgrey;'> n < / data-lsp> < / span> < span style="color: #000000"> : < / span> < span style="color: #00000FF"> typeof < / span> < span style="color: #00000FF"> typeof < / span> < span style="color: #00000FF"> typeof < / span> < span style="color: #001080"> < data-lsp lsp='let s: string' > s < / data-lsp> < / span> < span class='popover-prefix'> < / span> < span class='popover'> < div class='arrow'> < / div> let n: string < / span> < / code> < a class='playground-link'</pre>

href='https://www.typescriptlang.org/play/#code/DYUwLgBAzhC8ECIAWJjAPYINwChSQDsAuCMATwAc </div>

This isn't very useful for basic types, but combined with other type operators, you can use typeof to conveniently express many patterns. For an example, let's start by looking at the predefined type ReturnType<T>. It takes a *function type* and produces its return type:

 < div class='code-container' > < code > < div class='line' > < span style="color: #0000FF" > type < / span >

```
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Predicate = (x: unknown) => boolean' > Predicate < /data-lsp > </span > < span style = "color:
\#000000" = (</span> < span style="color: \#001080" > < data-lsp lsp='(parameter) x: unknown'
>x</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">unknown</span><span style="color: #000000">) </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color:
#267F99">boolean</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #0000FF">type</span><span style="color: #000000"> </span><span</pre>
style="color: #267F99"> < data-lsp lsp='type K = boolean' style='border-bottom: solid 2px
lightgrey;'>K</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#267F99"> < data-lsp lsp='type ReturnType&amp;lt;T extends (...args: any) => any> = T extends
(...args: any) => infer R? R: any' > ReturnType < /data-lsp > </span > < span style="color:
#000000"><</span><span style="color: #267F99"><data-lsp lsp='type Predicate = (x:
unknown) => boolean' > Predicate < /data-lsp > </span > < span style="color: #000000" > & gt;;
</span></div><span class='popover-prefix'> </span><span class='popover'><div
class='arrow'></div>type K = boolean</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBACgThAJgSwMYENjQLxQBQAeAXFAK4B2
</div>
```

If we try to use ReturnType on a function name, we see an instructive error:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function f():</pre>
{
 x: number;
 y: number;
}' >f</data-lsp></span><span
style="color: #000000">() {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #AF00DB">return</span><span style="color: #000000"> { </span>
<span style="color: #001080"> <data-lsp lsp='(property) x: number' >x</data-lsp>:</span> <span</pre>
style="color: #000000"> </span><span style="color: #098658">10</span><span style="color:
#000000">, </span> <span style="color: #001080"> <data-lsp lsp='(property) y: number'
>y</data-lsp>:</span><span style="color: #000000"> </span><span style="color:
#098658">3</span><span style="color: #000000"> };</span></div><div class='line'><span
style="color: #000000">}</span></div><div class='line'><span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type P = any' >P</data-lsp></span><span style="color: #000000"> = </span>
<span style="color: #267F99"> < data-lsp lsp='type ReturnType&amp;lt;T extends (...args: any) =>
any> = T extends (...args: any) => infer R ? R : any' > ReturnType < /data-lsp > </span > < span
style="color: #000000"><</span><span style="color: #267F99"><data-err><data-lsp lsp='any'
>f</data-lsp></data-err></span><span style="color: #000000">&gt;;</span></div><span
class="error"> < span> 'f' refers to a value, but is being used as a type here. Did you mean 'typeof f'?
</span><span class="code">2749</span></span><span class="error-behind">'f' refers to a
value, but is being used as a type here. Did you mean 'typeof f'?</span></code><a
class='playground-link'
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwHYAsBOAUAGYCuAdgMY/-</div>

Remember that *values* and *types* aren't the same thing. To refer to the *type* that the *value f* has, we use typeof:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span> <data-lsp lsp='function f():</pre> {
 x: number;
 y: number;
}' >f</data-lsp>() {</div><div class='line'> return { <data-lsp lsp='(property) x: number' >x</data-lsp>: <span</pre> style="color: #000000"> 10, <data-lsp lsp='(property) y: number' >y</data-lsp>: 3 };</div><div class='line'>}</div><div class='line'>type <data-lsp lsp='type P = {&#13; x: number;&#13; y: number;&#13;}' >P</data-lsp> = < data-lsp lsp='type ReturnType<T extends (...args: any) => any> = T extends (...args: any) => infer R ? R: any' > ReturnType < /data-lsp > & lt; typeof < data-lsp lsp='function f(): {&#13; x: number;&#13; y: number;
}' >f</data-lsp>>;</div> <div class='arrow'></div>type P = { x: number; y: number; }</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/GYVwdgxgLglg9mABMAFASkQbwFCMQJwFMoR8INE </div>

Limitations

TypeScript intentionally limits the sorts of expressions you can use typeof on.

Specifically, it's only legal to use typeof on identifiers (i.e. variable names) or their properties. This helps avoid the confusing trap of writing code you think is executing, but isn't:

<div
class='code-container'> <code> <div class='line'> // Meant to use =
ReturnType<typeof msgbox> </div> <div class='line'> <span style="color:
#0000FF">let
<data-lsp lsp='let shouldContinue: () => boolean' >shouldContinue</data-lsp> <span</pre>

style="color: #000000">: typeof : <data-lsp lsp='const msgbox: () => boolean' >msgbox</data-lsp> <data-err> (</data-err> "Are you sure you want to continue?"); </div> ',' expected. 1005 ',' expected. </code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFyglwAYMFYBQATSAYwBsBDaSUKmazUAB3WScXGkdC4oB+GoE5IA'>Try</div>

Indexed Access Types

We can use an *indexed access type* to look up a specific property on another type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Person = {
 age: number;
 name: string;
 alive: boolean;
}'
>Person</data-lsp></span><span style="color: #000000"> = { </span><span style="color:
#001080"> <data-lsp lsp='(property) age: number' >age </data-lsp> </span> <span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F9999"> number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999</span style="c
#000000">; </span> <span style="color: #001080"> <data-lsp lsp='(property) name: string'
>name</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">; </span><span style="color: #001080">
<data-lsp lsp='(property) alive: boolean' >alive</data-lsp></span><span style="color:</pre>
#000000">: </span> <span style="color: #267F99"> boolean </span style="color: #267F999"> boolean </span style="color: #267F9999> boolean </span style="color: #267F9999> boolean </span style="color: #267F9999> bo
#000000"> };</span></div><div class='line'><span style="color: #0000FF">type</span><span
style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type Age =
number' style='border-bottom: solid 2px lightgrey;'>Age</data-lsp></span><span style="color:
\#000000" = </span> < span style="color: \#267F99" > < data-lsp lsp='type Person = {&amp; \#13;
age: number;
 name: string;
 alive: boolean;
}' >Person</data-lsp>
</span><span style="color: #000000">[</span><span style="color: #A31515">"age"</span>
<span style="color: #000000">];</span></div><span class='popover-prefix'> </span><span</pre>
class='popover'> < div class='arrow'> </div>type Age = number </span> </code> < a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAChBOBnA9gOygXigbygQwHMIAuKVAVv
</div>
```

The indexing type is itself a type, so we can use unions, keyof, or other types entirely:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> type</span> <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='type l1 = string | number' style='border-bottom: solid 2px lightgrey;'> l1 </data-lsp </span> <span style="color: #000000"> = </span> <span style="color: #267F99"> <data-lsp lsp='type Person = {&amp;#13; age: number;&amp;#13; name: string;&amp;#13; alive: boolean;&amp;#13;}' > Person </data-lsp> </span> <span style="color: #000000"> [</span> <span style="color: #000000"> [</span> <span style="color: #A31515"> "age" </span> <span style="color: #000000"> ];</span> </div> <span class='popover-prefix'> </span> <span class='popover'> <div class='arrow'> </div> type l1 = string | number </span> <span style="color: #000000"> | </span> <span style="color: #000000"> | </span> <span style="color: #00000FF"> type </span> <span style="color: #00000FFT"> typ
```

```
boolean' style='border-bottom: solid 2px lightgrey;'>12</data-lsp></span><span style="color:
\#000000" = </span><span style="color: \#267F99"><data-lsp lsp='type Person = {&amp;#13;
age: number;
 name: string;
 alive: boolean;
}' > Person < /data-lsp>
</span><span style="color: #000000">[</span><span style="color: #0000FF">keyof</span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Person = {
 age: number;
 name: string;
 alive: boolean;
}'
>Person</data-lsp></span><span style="color: #000000">];</span></div><span
class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>type I2 =
string | number | boolean </span> < div class='line' > < span style="color: #0000FF" > type </span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
AliveOrName = & amp; quot; name& amp; quot; | & amp; quot; alive& amp; quot; |
>AliveOrName</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#A31515">"alive"</span><span style="color: #000000"> | </span><span style="color:
#A31515">"name"</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #0000FF">type</span><span style="color: #000000"> </span><span</pre>
style="color: #267F99"> < data-lsp lsp='type I3 = string | boolean' style='border-bottom: solid 2px
lightgrey;'>13 </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color:
#267F99"> < data-lsp lsp='type Person = {&amp;#13; age: number;&amp;#13; name:
string;
 alive: boolean;
}' > Person < /data-lsp > </span > < span style="color:
#000000">[</span><span style="color: #267F99"><data-lsp lsp='type AliveOrName =
"name" | "alive"' >AliveOrName</data-lsp></span>
<span style="color: #000000">];</span></div><span class='popover-prefix'> </span><span</pre>
class='popover'> < div class='arrow'> </div>type I3 = string | boolean < /span> < /code> < a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAChBOBnA9gOygXigbygQwHMIAuKVAVv
</div>
```

You'll even see an error if you try to index a property that doesn't exist:

```
class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> <div
class='code-container'> <code> <div class='line'> <span style="color: #00000FF"> type </span>
<span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='type l1 =
any' >l1 </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color:
#267F99"> <data-lsp lsp='type Person = {&amp;#13; age: number;&amp;#13; name:
string;&amp;#13; alive: boolean;&amp;#13;}' > Person </data-lsp> </span> <span style="color:
#000000">[</span> <span style="color: #A31515"> <data-err> &quot;alve&quot;</data-err>
</span> <span style="color: #000000">]; </span> </div> <span class="error"> <span> Property
'alve' does not exist on type 'Person'.</span> <span class="code"> 2339 </span> </span> </span> <span
class="error-behind"> Property 'alve' does not exist on type 'Person'.</span> </code> <a
class='playground-link'</pre>
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYME4BQAXATwAdJQAFG</div>

Another example of indexing with an arbitrary type is using number to get the type of an array's elements. We can combine this with type of to conveniently capture the element type of an array literal:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const</span>
<span style="color: #000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const</pre>
MyArray: {
 name: string;
 age: number;
}[]' > MyArray < /data-lsp>
</span><span style="color: #000000"> = [</span></div><div class='line'><span style="color:
#000000"> { </span> < span style="color: #001080"> < data-lsp lsp='(property) name: string'
>name</data-lsp>:</span><span style="color: #000000"> </span><span style="color:
#A31515">"Alice"</span><span style="color: #000000">, </span><span style="color:
#001080"> <data-lsp lsp='(property) age: number' >age </data-lsp>: </span> <span style="color:
#000000"> </span><span style="color: #098658">15</span><span style="color: #000000"> },
</span> </div> <div class='line'> <span style="color: #000000"> { </span> <span style="color:
#001080"> < data-lsp lsp='(property) name: string' > name < /data-lsp >: </span> < span style="color:
#000000"> </span><span style="color: #A31515"> "Bob" </span> < span style="color: #000000">,
</span><span style="color: #001080"><data-lsp lsp='(property) age: number' >age</data-lsp>:
</span><span style="color: #000000"> </span><span style="color: #098658">23</span><span
style="color: #000000"> }, </span> </div> < div class='line'> < span style="color: #000000"> {
</span><span style="color: #001080"><data-lsp lsp='(property) name: string' >name</data-
lsp>:</span><span style="color: #000000"> </span><span style="color: #A31515"> "Eve"
</span><span style="color: #000000">, </span><span style="color: #001080"> < data-lsp
lsp='(property) age: number' >age</data-lsp>:</span><span style="color: #000000"> </span>
<span style="color: #098658">38</span><span style="color: #000000"> },</span></div><div</pre>
class='line'><span style="color: #000000">];</span></div> <div class='line'><span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type Person = {&amp;#13; name: string;&amp;#13; age: number;&amp;#13;}'</pre>
>Person</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#0000FF">typeof</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='const MyArray: {&amp;#13; name: string;&amp;#13; age: number;&amp;#13;}[]'</pre>
>MyArray</data-lsp></span><span style="color: #000000">[</span><span style="color:
#001080">number </span> < span style="color: #000000">]; </span> </div> < span
class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>type Person =
{ name: string; age: number; }</span> < div class='line'> < span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type Age = number' style='border-bottom: solid 2px lightgrey;'>Age</data-lsp>
</span><span style="color: #000000"> = </span><span style="color: #0000FF">typeof</span>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='const</pre>
MyArray: {
 name: string;
 age: number;
}[]' > MyArray < /data-lsp>
</span><span style="color: #000000">[</span><span style="color: #001080">number</span>
<span style="color: #000000">][</span><span style="color: #A31515">"age"</span><span</pre>
style="color: #000000">];</span></div><span class='popover-prefix'> </span><span
```

class='popover'> < div class='arrow'> < /div> type Age = number < /span> < div class='line'> < span style="color: #008000"> // Or < /span> < /div> < div class='line'> < span style="color: #267F99"> < data-lsp lsp='type Age2 = number' style='border-bottom: solid 2px lightgrey;'> Age2 < /data-lsp < < /span> < span style="color: #000000"> = < span style="color: #267F99"> < data-lsp lsp='type Age2 = number' style='border-bottom: solid 2px lightgrey;'> Age2 < /data-lsp> < /span> < span style="color: #000000"> = < span style="color: #267F99"> < data-lsp lsp='type Person = {&#13; name: string;&#13; age: number;&#13;}'> Person < /data-lsp> < /span> < span style="color: #000000"> [< /span> < span style="color: #A31515"> "age" < /span> < span style="color: #000000">]; < /span> < /div> < span class='popover-prefix'> < /span> < /code> < a class='playground-link'

href='https://www.typescriptlang.org/play/#code/MYewdgzgLgBAsgTwIICcUEMEwLwwNoBQMMA3jGO </div>

You can only use types when indexing, meaning you can't use a const to make a variable reference:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const <data-lsp lsp='const key:</pre> "age"' >key </data-lsp> < span style="color: #000000"> = "age";</div><div</pre> class='line'>type < data-lsp lsp='type Age = any' > Age < /data-lsp > < span</pre> style="color: #000000"> = <data-lsp lsp='type Person = {
 age: number;
 name: string;
 alive: boolean;
}' >Person</data-lsp>[<data-err> <data-lsp lsp='any' >key </data-lsp> </data-err>];</div>Type 'any' cannot be used as an index type.</br>'key' refers to a value, but is being used as a type here. Did you mean 'typeof key'?2538
2749Type 'any' cannot be used as an index type.</br>'key' refers to a value, but is being used as a type here. Did you mean 'typeof key'?</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYDMAOdB2AFgE4AoAFw WbwA2agG5KJcODsi82AX2mkQoALSOAxiPKP7pJ6xWgA1pEoOUAAiAUhgmypaUABBQSDGJFYAbX9KAI </div>

However, you can use a type alias for a similar style of refactor:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type </ span> < span style="color: #000000"> </ span> < span style="color: #267F99"> < data-lsp lsp='type key = & amp;quot; age& amp;quot; > key < / data-lsp> </ span> < span style="color: #000000"> = </ span> < span style="color: #000000"> ; </ span> < / div> < div class='line'> < span style="color: #000000"> ; </ span> < span style="color: #000000"> < / span> < span style="color: #000000"> < span style="color: #0

 < data-lsp lsp='type Age = number' > Age < /data-lsp >
 = < span style="color: #267F99"> < data-lsp lsp='type
Person = {&#13; age: number;&#13; name: string;&#13; alive: boolean;&#13;}'
> Person < /data-lsp > < span style="color: #000000"> [< span style="color: #267F99"> < data-lsp lsp='type key = &quot;age&quot;' > key < /data-lsp> < span style="color: #000000">]; < /div> </code> < a class='playground-link'

Conditional Types

At the heart of most useful programs, we have to make decisions based on input. JavaScript programs are no different, but given the fact that values can be easily introspected, those decisions are also based on the types of the inputs. *Conditional types* help describe the relation between the types of inputs and outputs.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
Animal' > Animal < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) Animal.live(): void' >live</data-lsp></span><span style="color: #000000">():
</span><span style="color: #267F99">void</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000">}</span></div><div class='line'><span
style="color: #0000FF">interface</span><span style="color: #000000"> </span><span
style="color: #267F99"> < data-lsp lsp='interface Dog' > Dog < /data-lsp > </span> < span
style="color: #000000"> </span><span style="color: #0000FF">extends</span><span
style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface Animal'
>Animal</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='(method)</pre>
Dog.woof(): void' >woof</data-lsp></span><span style="color: #000000">(): </span><span
style="color: #267F99">void</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000">}</span></div> <div class='line'><span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type Example1 = number' style='border-bottom: solid 2px</pre>
lightgrey;'>Example1</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #267F99"> < data-lsp lsp='interface Dog' > Dog < /data-lsp > </span> < span
style="color: #000000"> </span><span style="color: #0000FF">extends</span><span
style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface Animal'
>Animal</data-lsp></span><span style="color: #000000">? </span><span style="color:
#267F99">number</span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">;</span></div><span class='popover-
prefix'> </span><span class='popover'><div class='arrow'></div>type Example1 =
number</span> <div class='line'><span style="color: #0000FF">type</span><span style="color:
#000000"> </span><span style="color: #267F99"> <data-lsp lsp='type Example2 = string'
style='border-bottom: solid 2px lightgrey;'> Example2 < /data-lsp> < /span> < span style="color:
#000000"> = </span><span style="color: #267F99"> <data-lsp lsp='interface RegExp'
>RegExp</data-lsp></span><span style="color: #000000"> </span><span style="color:
#0000FF">extends</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='interface Animal' > Animal < /data-lsp> < /span> < span style="color:
```

#000000"> ? number : string ; </div> <div class='arrow'> </div> type Example2 = string </code> Try </div>

Conditional types take a form that looks a little like conditional expressions (condition ? trueExpression : falseExpression) in JavaScript:

When the type on the left of the extends is assignable to the one on the right, then you'll get the type in the first branch (the "true" branch); otherwise you'll get the type in the latter branch (the "false" branch).

From the examples above, conditional types might not immediately seem useful - we can tell ourselves whether or not Dog extends Animal and pick number or string! But the power of conditional types comes from using them with generics.

For example, let's take the following createLabel function:

<div class='code-container'> <code> <div class='line'> interface <data-lsp lsp='interface ldLabel' >IdLabel </data-lsp> { </div> <div class='line'> <data-lsp lsp='(property) ldLabel.id: number' >id </data-lsp> : ; </div> <div class='line'> ; interface </

```
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='(property) NameLabel.name: string'
>name</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000"> </span><span style="color:
#008000">/* other fields */</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000">}</span></div> <div class='line'><span style="color:
#0000FF">function</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='function createLabel(id: number): IdLabel (+2 overloads)'
>createLabel</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) id: number' > id < /data-lsp > </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F999999
#000000">): </span><span style="color: #267F99"> < data-lsp lsp='interface IdLabel'
>IdLabel</data-lsp></span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #0000FF">function</span><span style="color: #000000"> </span><span</pre>

(+2 overloads)' > createLabel < /data-lsp > </span > < span style = "color: #000000" > (</span > < span
style="color: #001080"> < data-lsp lsp='(parameter) nameOrld: string | number'
>nameOrld</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000"> | </span><span style="color:
#267F99">number</span><span style="color: #000000">): </span><span style="color:
#267F99"> < data-lsp lsp='interface IdLabel' > IdLabel < /data-lsp > </span> < span style="color:
#000000"> | </span> <span style="color: #267F99"> <data-lsp |sp='interface NameLabel'
>NameLabel</data-lsp></span><span style="color: #000000"> {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color:
#AF00DB">throw</span><span style="color: #000000"> </span><span style="color:
#A31515">"unimplemented"</span><span style="color: #000000">;</span></div><div
```

class='line'> } </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgJIBMAycBGEA2yA3gFDLLDoI Ck3Dy8fPwCgiETQ3X4DI1M45FV1XAJk909vX39A4PL8XL0AeSgMAuMQMwAfWkZmYoTG5D7S7MbK1J </div>

These overloads for createLabel describe a single JavaScript function that makes a choice based on the types of its inputs. Note a few things:

- 1. If a library has to make the same sort of choice over and over throughout its API, this becomes cumbersome.
- 2. We have to create three overloads: one for each case when we're *sure* of the type (one for string and one for number), and one for the most general case (taking a string | number). For every new type createLabel can handle, the number of overloads grows exponentially.

Instead, we can encode that logic in a conditional type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
NameOrld<T extends string | number > = T extends number ? IdLabel : NameLabel'
>NameOrld</data-lsp></span><span style="color: #000000">&lt;</span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) T in type NameOrld&amp;lt;T extends string |
number>' >T</data-lsp></span><span style="color: #000000"> </span><span style="color:
#0000FF">extends</span><span style="color: #000000"> </span><span style="color:
#267F99">number</span><span style="color: #000000"> | </span><span style="color:
#267F99">string</span><span style="color: #000000">&gt; = </span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) T in type NameOrld&amp;lt;T extends string |
number>' >T</data-lsp></span><span style="color: #000000"> </span><span style="color:
#0000FF">extends</span><span style="color: #000000"> </span><span style="color:
#267F99">number</span></div><div class='line'><span style="color: #000000">? </span>
<span style="color: #267F99"> < data-lsp lsp='interface IdLabel' > IdLabel < /data-lsp > </span>
</div><div class='line'><span style="color: #000000"> : </span><span style="color: #267F99">
<data-lsp lsp='interface NameLabel' > NameLabel < /data-lsp > </span > < span style="color:</pre>
#000000">;</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/JYOwLgpgTgZghgYwgAgJIBMAycBGEA2yA3gFDLLDoI
</div>
```

We can then use that conditional type to simplify out overloads down to a single function with no overloads.

```
 < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
< span style="color: #795E26"> < data-lsp lsp='function</pre>
```

```
createLabel<T extends string | number>(idOrName: T): NameOrld&amp;lt;T>'
>createLabel</data-lsp></span><span style="color: #000000">&lt;</span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) T in createLabel&amp;lt;T extends string | number>
(idOrName: T): NameOrld<T>' >T</data-lsp></span><span style="color: #000000">
</span><span style="color: #0000FF">extends</span><span style="color: #000000"> </span>
<span style="color: #267F99">number</span><span style="color: #000000"> | </span><span</pre>
style="color: #267F99">string</span><span style="color: #000000">&gt;(</span><span
style="color: #001080"> < data-lsp lsp='(parameter) idOrName: T extends string | number'
>idOrName</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) T in createLabel&amp;lt;T extends string | number>

Conditional Type Constraints

Often, the checks in a conditional type will provide us with some new information. Just like with narrowing with type guards can give us a more specific type, the true branch of a conditional type will further constraint generics by the type we check against.

For example, let's take the following:

In this example, TypeScript errors because T isn't known to have a property called message. We could constrain T, and TypeScript would no longer complain:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type
<span style="color: #000000"> </span> < span style="color: #267F99"> < data-lsp lsp='type</pre>
MessageOf&amp;lt;T extends { message: unknown; }> = T[&amp;quot;message&amp;quot;]'
>MessageOf < /data-lsp> < /span> < span style="color: #000000"> &lt; < /span> < span style="color: #267F99"> < data-lsp lsp='(type parameter) T in type MessageOf&amp;lt;T extends { message: unknown; }>' > T < /data-lsp> < /span> < span style="color: #000000"> <
```

```
style="color: #000000">: </span><span style="color: #267F99">unknown</span><span
style="color: #000000"> \}> = </span><span style="color: #267F99"><data-lsp lsp='(type lsp=')
parameter) T in type MessageOf&It;T extends { message: unknown; }>' >T</data-lsp></span>
<span style="color: #000000">[</span><span style="color: #A31515">"message"</span><span</pre>
style="color: #000000">];</span></div> <div class='line'><span style="color:
#0000FF">interface</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='interface Email' > Email < /data-lsp > </span> < span style="color:
#000000"> {</span> </div> <div class='line'> <span style="color: #000000"> </span> <span
style="color: #001080"> < data-lsp lsp='(property) Email.message: string' > message < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">string</span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div> <div class='line'><span style="color: #0000FF">interface</span><span
style="color: #000000"> </span><span style="color: #267F99"> < data-lsp lsp='interface Dog'
>Dog</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='(method)</pre>
Dog.bark(): void' >bark</data-lsp></span><span style="color: #000000">(): </span><span
style="color: #267F99">void</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000">}</span></div> <div class='line'><span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type EmailMessageContents = string' style='border-bottom: solid 2px</pre>
lightgrey;'>EmailMessageContents</data-lsp></span><span style="color: #000000"> = </span>
<span style="color: #267F99"> < data-lsp lsp='type MessageOf&amp;lt;T extends { message:</pre>
unknown; }> = T["message"]' > MessageOf</data-lsp></span><span
style="color: #000000"><</span><span style="color: #267F99"><data-lsp lsp='interface Email'
>Email</data-lsp></span><span style="color: #000000">&gt;;</span></div><span
class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>type
EmailMessageContents = string</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAshDO8CGBzCB5AZgHgCpQgA9gIA7AE3
</div>
```

However, what if we wanted MessageOf to take any type, and default to something like never if a message property isn't available? We can do this by moving the constraint out and introducing a conditional type:

```
#0000FF">extends</span><span style="color: #000000"> { </span><span style="color:
#001080"> < data-lsp lsp='(property) message: unknown' > message < /data-lsp > </span> < span
style="color: #000000">: </span><span style="color: #267F99">unknown</span><span
style="color: #000000"> }? </span><span style="color: #267F99"> <data-lsp lsp='(type
parameter) T in type MessageOf<T>' >T</data-lsp></span><span style="color:
#000000">[</span><span style="color: #A31515">"message"</span><span style="color:
#000000">]: </span> < span style="color: #267F99"> never </span style="color: #267F999"> never </span style="color: #267F9999"> never </span style="color: #267F9999"> never </span style="color: #267F
#000000">;</span></div> <div class='line'><span style="color: #0000FF">interface</span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
Email' > Email < /data-lsp > </span > < span style = "color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) Email.message: string' > message</data-lsp> </span> < span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #0000FF">interface</span><span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='interface Dog' > Dog</data-lsp></span>
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='(method) Dog.bark(): void' >bark</data-

}? T["message"]: never' > MessageOf < /data-
lsp></span><span style="color: #000000">&lt;</span><span style="color: #267F99"><data-lsp
lsp='interface Dog' > Dog < /data-lsp > </span > < span style="color: #000000" > & qt;; < /span > < /div >
<span class='popover-prefix'> </span><span class='popover'> <div class='arrow'> </div>type
DogMessageContents = never</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAshDO8CGBzCB5AZgHgCoD4oBeKXKCAI
</div>
```

Within the true branch, TypeScript knows that T will have a message property.

As another example, we could also write a type called Flatten that flattens array types to their element types, but leaves them alone otherwise:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type</pre> Flatten<T> = T extends any[] ? T[number] : T' > Flatten < /data-lsp > <<data-lsp lsp='(type parameter) T in type Flatten<T>' >T</data-lsp>> = <data-lsp lsp='(type parameter) T in type Flatten<T>' >T</data-lsp> extends any[] ? < data-lsp lsp='(type parameter) T in type Flatten&lt;T>' >T</datalsp>[number] : < data-lsp lsp='(type parameter) T in type Flatten&lt;T>' >T</data-lsp> ;</div> <div class='line'><span style="color:</pre> #008000">// Extracts out the element type.</div><div class='line'>type <data-lsp lsp='type Str = string' style='border-bottom: solid 2px lightgrey;'>Str</data-lsp> = <data-lsp lsp='type Flatten<T> = T extends any[] ? T[number] : T' > Flatten < /data-lsp > < span style="color: #000000"><string[]&qt;;</div> <div class='arrow'></div>type Str = string <div class='line'>// Leaves the type alone.</div><div class='line'>type < data-lsp lsp='type Num = number' style='border-bottom: solid 2px lightgrey;'>Num</data-lsp> = < data-lsp lsp='type Flatten&lt;T> = T extends any[] ? T[number] : T' >Flatten</data-lsp><number&qt;;</div> < div class='arrow'> </div>type Num = number</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAYgNgQ2MCA7APAFQHxQLxSZQQAeKqA </div>

When Flatten is given an array type, it uses an indexed access with number to fetch out string[] 's element type. Otherwise, it just returns the type it was given.

Inferring Within Conditional Types

We just found ourselves using conditional types to apply constraints and then extract out types. This ends up being such a common operation that conditional types make it easier.

Conditional types provide us with a way to infer from types we compare against in the true branch using the infer keyword. For example, we could have inferred the element type in Flatten instead of fetching it out "manually" with an indexed access type:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Flatten<Type> = Type extends (infer Item)[] ? Item : Type' > Flatten < /data-lsp > < /span>
<span style="color: #000000">&lt;</span><span style="color: #267F99"><data-lsp lsp='(type</pre>
parameter) Type in type Flatten<Type>' >Type</data-lsp></span><span style="color:
#000000">> = </span><span style="color: #267F99"><data-lsp lsp='(type parameter) Type in
type Flatten<Type>' >Type</data-lsp></span><span style="color: #000000"> </span>
<span style="color: #0000FF">extends</span><span style="color: #000000"> </span><span</pre>
style="color: #267F99"> < data-lsp lsp='interface Array&amp;lt;T>' > Array < /data-lsp> < /span>
<span style="color: #000000">&lt;</span><span style="color: #0000FF">infer</span><span</pre>
style="color: #000000"> </span><span style="color: #267F99"> < data-lsp lsp='(type parameter)
#267F99"> < data-lsp lsp='(type parameter) ltem' > ltem < /data-lsp > </span> < span style="color:
#000000">: </span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in type
Flatten<Type>' >Type</data-lsp></span><span style="color: #000000">;</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAYgNgQ2MCA7APAFXBAfFAXim0iggA8VL
</div>
```

Here, we used the infer keyword to declaratively introduce a new generic type variable named Item instead of specifying how to retrieve the element type of T within the true branch. This frees us from having to think about how to dig through and probing apart the structure of the types we're interested in.

We can write some useful helper type aliases using the infer keyword. For example, for simple cases, we can extract the return type out from function types:

```
class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type </ span>
  < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='type
  GetReturnType&amp;lt;Type> = Type extends (...args: never[]) => infer Return ? Return : never'
  > GetReturnType</data-lsp> < / span> < span style="color: #000000"> & lt; < / span> < span
  style="color: #267F99"> < data-lsp lsp='(type parameter) Type in type
  GetReturnType&amp;lt;Type>' > Type < / data-lsp lsp='(type parameter) Type in type
  GetReturnType&amp;lt;Type>' > Type < / data-lsp lsp='(type parameter) Type in type
  GetReturnType&amp;lt;Type>' > Type < / data-lsp lsp='(type parameter) Type in type
  GetReturnType&amp;lt;Type>' > Type < / data-lsp lsp='(type parameter) Type in type

class='arrow'> </div>type Bools = boolean[] </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBA4hwCV4FcBOA7AKuCAebkAfFALxQHQQ </div>

When inferring from a type with multiple call signatures (such as the type of an overloaded function), inferences are made from the *last* signature (which, presumably, is the most permissive catch-all case). It is not possible to perform overload resolution based on a list of argument types.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> declare < / span> function<span</pre> style="color: #000000"> <data-lsp lsp='function stringOrNum(x: string): number (+2 overloads)' > stringOrNum < /data-lsp > < span style="color: #000000">(<data-lsp lsp='(parameter) x: string' >x</data-lsp>: string): number;</div><div class='line'> declare <span</pre> style="color: #0000FF">function < data-lsp lsp='function stringOrNum(x: number): string (+2 overloads)' >stringOrNum</data-lsp>(< data-lsp lsp='(parameter) x: number' > x < / data-lsp > < / span > < span style="color: #000000">: number number number number </span style="color: #267F999999</span style="color: #267F99999</span style="color: #267F9999999): string;</div><div class='line'>declare function<span</pre> style="color: #000000"> < span style="color: #795E26"> < data-lsp lsp='function stringOrNum(x: string | number): string | number (+2 overloads)' > stringOrNum < /data-lsp> (<data-lsp lsp='(parameter) x: string | number' >x</data-lsp>: string | number): <span</pre> style="color: #267F99">string | number;</div> <div class='line'>type < data-lsp lsp='type T1 = string | number' style='border-bottom:</pre> solid 2px lightgrey;'>T1 </data-lsp> = < data-lsp lsp='type ReturnType&lt;T extends (...args: any) => any> = T extends (...args: any) => infer R ? href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEAzArgOzAFwJYHtXwGcMYtUBzAeR@
</div>

Distributive Conditional Types

When conditional types act on a generic type, they become *distributive* when given a union type. For example, take the following:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='type ToArray&lt;Type> = Type extends any ? Type[] : never' > ToArray</data-lsp lsp='(type parameter) Type in type ToArray&lt;Type>' > Type</data-lsp> < / span> < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in type ToArray&lt;Type>' > Type</data-lsp lsp='(type parameter) Type in type ToArray&lt;Type>' > Type</data-lsp lsp='(type parameter) Type in type ToArray&lt;Type>' > Type</data-lsp> < span style="color: #000000"> < / span> < span style="color: #000000"> < / span> < span style="color: #000000"> < / span> < span style="color: #267F99"> any < / span> < span style="color: #000000"> ? < / span> < span style="color: #267F99"> ny < / span> < span style="color: #267F99"> ny < / span> < span style="color: #267F99"> ny < s

If we plug a union type into ToArray, then the conditional type will be applied to each member of that union.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type</pre> ToArray<Type> = Type extends any ? Type[] : never' >ToArray</data-lsp><<data-lsp lsp='(type parameter) Type in type ToArray<Type>' > Type</data-lsp> < span style="color: #000000">> = <data-lsp lsp='(type parameter) Type in type ToArray<Type>' >Type</data-lsp> extends <span</pre> style="color: #267F99">any? < data-lsp lsp='(type parameter) Type in type ToArray&lt;Type>' > Type < /data-lsp> []: never ;</div> <div class='line'><span style="color:</pre> #0000FF">type <data-lsp lsp='type StrArrOrNumArr = string[] | number[]' style='border-bottom: solid 2px</pre> lightgrey;'>StrArrOrNumArr</data-lsp> = <span

```
style="color: #267F99"> < data-lsp lsp='type ToArray&amp;lt;Type> = Type extends any ? Type[] : never' > ToArray < /data-lsp > </span > <span style="color: #000000"> &lt; </span > <span style="color: #267F99"> string </span > <span style="color: #000000"> | </span > <span style="color: #267F99"> number </span > <span style="color: #000000"> &gt;; </span > </div> <span class='popover-prefix'> </span > <span class='popover'> <div class='arrow'> </div> type StrArrOrNumArr = string[] | number[] </span > </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAKg9gQQE5IIYgDw3BAfFAXIhyggA9gIA7# </div>
```

What happens here is that StrOrNumArray distributes on:

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAysBOBBe8Dy8ByBXAts+UAvAFBRQD05U </div>

and maps over each member type of the union, to what is effectively:

```
class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> </div
class='code-container'> <code> <div class='line'> <span style="color: #000000"> </span> <span
style="color: #001080"> <data-lsp lsp='type ToArray&amp;lt;Type> = Type extends any ? Type[] :
never' > ToArray </data-lsp> </span> <span style="color: #000000"> &lt; </span> <span
style="color: #001080"> string </span> <span style="color: #000000"> &gt; | </span> <span
style="color: #001080"> <data-lsp lsp='type ToArray&amp;lt;Type> = Type extends any ? Type[] :
never' > ToArray </data-lsp> </span> <span style="color: #000000"> &lt; </span> <span
style="color: #001080"> number </span> <span style="color: #000000"> &gt;; </span> </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAKg9gQQE5IIYgDw3BAfFAXlhyggA9gIA7#</pre>
```

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAKg9gQQE5IIYgDw3BAfFAXIhyggA9gIA7*I* </div>

which leaves us with:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #000000"> </span> <span style="color: #001080"> string </span> <span style="color: #000000">[] | </span> <span style="color: #001080"> number </span> <span style="color: #000000"> []; </span> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAysBOBBe8Dy8ByBXAts+UAvAFBRQD05l </div>
```

Typically, distributivity is the desired behavior. To avoid that behavior, you can surround each side of the extends keyword with square brackets.

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type</pre> ToArrayNonDist<Type> = [Type] extends [any] ? Type[] : never' > ToArrayNonDist</datalsp><<data-lsp lsp='(type parameter) Type in type ToArrayNonDist<Type>' > Type < /data-lsp> < /span> &qt; = [<data-lsp lsp='(type parameter) Type in type ToArrayNonDist<Type>' >Type</data-lsp>] extends<span</pre> style="color: #000000"> [any1? < span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in type ToArrayNonDist<Type>' > Type</data-lsp>[]: never; </div> <div class='line'> // 'StrOrNumArr' is no longer a union.</div><div class='line'>type <data-lsp lsp='type</pre> StrOrNumArr = (string | number)[]' style='border-bottom: solid 2px lightgrey;'>StrOrNumArr</data-lsp> = < data-lsp lsp='type ToArrayNonDist&lt;Type> = [Type] extends [any] ? Type[] : never' >ToArrayNonDist</data-lsp>< string | <span</pre> style="color: #267F99">number>;</div> < div class='arrow'> </div>type StrOrNumArr = (string | number)[]</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAKg9gQQE5IIYgHJwHYBECWAzsADwzgQ </div>

Mapped Types

When you don't want to repeat yourself, sometimes a type needs to be based on another type.

Mapped types build on the syntax for index signatures, which are used to declare the types of properties which has not been declared ahead of time:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
OnlyBoolsAndHorses = {
 [key: string]: boolean | Horse;
}'
>OnlyBoolsAndHorses</data-lsp></span><span style="color: #000000"> = {</span></div><div
class='line'><span style="color: #000000"> [</span><span style="color: #001080"> <data-lsp
lsp='(parameter) key: string' > key < /data-lsp> < /span> < span style="color: #000000">: </span>
<span style="color: #267F99">string</span><span style="color: #000000">]: </span><span</pre>
style="color: #267F99">boolean</span><span style="color: #000000"> | </span><span
style="color: #267F99"> < data-lsp lsp='type Horse = {}' > Horse < /data-lsp> < /span> < span
style="color: #000000">;</span></div><div class='line'><span style="color: #000000">};
</span></div> <div class='line'><span style="color: #0000FF">const</span><span style="color:
#000000"> </span> <span style="color: #0070C1"> <data-lsp lsp='const conforms:
OnlyBoolsAndHorses' >conforms</data-lsp></span><span style="color: #000000">: </span>
<span style="color: #267F99"> < data-lsp lsp='type OnlyBoolsAndHorses = {&amp;#13; [key:</pre>
string]: boolean | Horse;
}' > OnlyBoolsAndHorses < /data-lsp > </span > <span
style="color: #000000"> = {</span></div><div class='line'> < span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='(property) del: true' >del</data-lsp>:
</span><span style="color: #000000"> </span><span style="color: #0000FF">true</span>
<span style="color: #000000">,</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='(property) rodney: false' >rodney</data-
lsp>:</span><span style="color: #000000"> </span><span style="color:
#0000FF">false</span><span style="color: #000000">,</span></div><div class='line'><span
style="color: #000000">};</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAEg9gJwM7QLxQN4F8DcAoAegKgFoyBj/
</div>
```

A mapped type is a generic type which uses a union created <u>via a keyof</u> to iterate through the keys of one type to create another:

In this example, OptionFlags will take all the properties from the type Type and change their values to be a boolean.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
FeatureFlags = {
 darkMode: () => void;
 newUserProfile: () =>
void;
}' >FeatureFlags</data-lsp></span><span style="color: #000000"> = {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='(property) darkMode: () => void' >darkMode</data-lsp></span><span
style="color: #000000">: () </span><span style="color: #0000FF">=&gt;</span><span
style="color: #000000"> </span><span style="color: #267F99">void</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #795E26"> < data-lsp lsp='(property) newUserProfile: () => void'
>newUserProfile</data-lsp></span><span style="color: #000000">: () </span><span
style="color: #0000FF">=&qt;</span><span style="color: #000000"> </span><span
style="color: #267F99">void</span><span style="color: #000000">;</span></div><div

class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>type
FeatureOptions = { darkMode: boolean; newUserProfile: boolean; }</span></code><a
class='playground-link'
```

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBA8mwEsD2A7AzgMQDYEMDmaAPACrgQ </div>

Mapping Modifiers

There are two additional modifiers which can be applied during mapping: readonly and ? which affect mutability and optionality respectively.

You can remove or add these modifiers by prefixing with - or + . If you don't add a prefix, then + is assumed.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000">// Removes
'readonly' attributes from a type's properties</span></div><div class='line'>
<span style="color: #0000FF">type</span><span style="color: #000000"> </span><span</pre>
style="color: #267F99"> < data-lsp lsp='type CreateMutable&amp;lt;Type> = { -readonly [Property
in keyof Type]: Type[Property]; }' > CreateMutable < /data-lsp > </span > < span style = "color:
#000000"><</span><span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in

</div>
```

Key Remapping via as

In TypeScript 4.1 and onwards, you can re-map keys in mapped types with an as clause in a mapped type:

```
 <div
class="language-id">ts</div> <div class='code-container'> <code> <div class='line'> <span
style="color: #0000FF"> type</span> <span style="color: #000000"> </span> <span style="color: #000000"> &lt; </span> <
span style="color: #000000"> &lt; </span> <
span style="color: #000000"> &gt; = {</span> <
/div> <div class='line'> <span style="color: #000000"> [</span> <span style="color: #00000"> </span> <span style="color: #267F99"> Type</span> <span style="color: #000000"> </span> <span style="color: #267F99"> Type</span> <span style="color: #000000"> </span> <span style="color: #267F99"> NewKeyType</span> <span style="color: #000000"> [</span> <span style="color: #267F99"> Type</span> <span style="color: #000000"> [</span> </span> </span style="color: #267F99"> Type</span> <span style="color: #000000"> [</span> </span> </
```

You can leverage features like <u>template literal types</u> to create new property names from prior ones:

```
 < div
class='code-container'> < code> < div class='line'> < span style="color: #00000FF"> type < / span>
< span style="color: #267F99"> < data-lsp lsp='type</pre>
```

```
Getters<Type> = { [Property in keyof Type as `get${Capitalize&amp;lt;string &amp;amp;
Property>}`]: () => Type[Property]; }' > Getters < /data-lsp > </span > <span style="color:
#000000"><</span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in
type Getters<Type>' >Type</data-lsp></span><span style="color: #000000">&qt; =
{</span></div><div class='line'><span style="color: #000000"> [</span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Property' > Property < /data-lsp > </span> < span
style="color: #000000"> </span><span style="color: #0000FF">in</span><span style="color:
#000000"> </span><span style="color: #0000FF">keyof</span><span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='(type parameter) Type in type
Getters<Type>' >Type</data-lsp></span><span style="color: #000000"> </span><span
style="color: #AF00DB">as</span><span style="color: #000000"> </span><span style="color:
#A31515">`get</span><span style="color: #0000FF">${</span><span style="color: #267F99">
<data-lsp lsp='type Capitalize&amp;lt;S extends string> = intrinsic' >Capitalize</data-lsp>
</span><span style="color: #000000FF">&lt;</span><span style="color:
#267F99">string</span><span style="color: #000000FF"> </span><span style="color:
#000000">&</span><span style="color: #000000FF"> </span><span style="color: #267F99">
<data-lsp lsp='(type parameter) Property' > Property < / data-lsp > </span > < span style="color:</pre>
#000000FF">></span><span style="color: #0000FF">}</span><span style="color: #0000FF">}
#A31515">`</span><span style="color: #000000">]: () </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color: #267F99">

```

Further Exploration

Mapped types work well with other features in this type manipulation section, for example here is a mapped type using a conditional type which returns either a true or false depending on whether an object has the property pii set to the literal true:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
ExtractPII<Type> = { [Property in keyof Type]: Type[Property] extends {&amp;#13; pii:
true;
}? true: false; }' > ExtractPII < /data-lsp > </span > < span style="color: #000000" > & lt;
</span><span style="color: #267F99"><data-lsp lsp='(type parameter) Type in type
ExtractPII<Type>' >Type</data-lsp></span><span style="color: #000000">&qt; =
{</span> </div> < div class='line'> < span style="color: #000000"> [</span> < span style="color:
#267F99"> < data-lsp lsp='(type parameter) Property' > Property < /data-lsp > </span> < span
style="color: #000000"> </span><span style="color: #0000FF">in</span><span style="color:
#000000"> </span><span style="color: #0000FF">keyof</span><span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='(type parameter) Type in type
ExtractPII<Type>' >Type</data-lsp></span><span style="color: #000000">]: </span>
<span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in type</pre>

```

Template Literal Types

Template literal types build on <u>string literal types</u>, and have the ability to expand into many strings via unions.

They have the same syntax as <u>template literal strings in JavaScript</u>, but are used in type positions. When used with concrete literal types, a template literal produces a new string literal type by concatenating the contents.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type World</pre>
= "world"' > World</data-lsp></span><span style="color: #000000"> =
</span><span style="color: #A31515"> "world" </span> < span style="color: #000000">; </span>
</div> <div class='line'> <span style="color: #0000FF">type</span> <span style="color:
#000000"> </span><span style="color: #267F99"> <data-lsp lsp='type Greeting =
"hello world"' > Greeting < /data-lsp > </span > < span style="color: #000000" >
= </span> < span style="color: #A31515"> `hello </span> < span style="color:
#0000FF">${</span><span style="color: #267F99"><data-lsp lsp='type World =
"world"' > World < /data-lsp > </span > < span style="color: #0000FF" > }
</span><span style="color: #A31515">`</span><span style="color: #000000">;</span></div>
<span class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>type
Greeting = "hello world"</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBA6g9gJwDYBMoF4oCIDujVYDcAUMaJFAC
</div>
```

When a union is used in the interpolated position, the type is the set of every possible string literal that could be represented by each union member:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> type</span> <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='type EmailLocaleIDs = &amp;quot;welcome_email&amp;quot; | &amp;quot;email_heading&amp;quot;' >EmailLocaleIDs </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #000000"> | </span> <span style="color: #000000"> | </span> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #00000FF"> type </span> <span style="color: #000000"> <</span> <span style="color: #000000"> <</span> <span style="color: #000000"> <</span> <span style="color: #000000"> = </span> </sp
```

```
<div class='line'><span style="color: #0000FF">type</span><span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='type AllLocaleIDs =
"welcome email id" | "email heading id" |
"footer title id" | "footer sendoff id"
>AllLocaleIDs</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#A31515">`</span><span style="color: #0000FF">${</span><span style="color: #267F99">
<data-lsp lsp='type EmailLocaleIDs = &amp;quot;welcome email&amp;quot; |</pre>
"email heading"' > EmailLocaleIDs < /data-lsp > </span > < span style="color:
#000000FF"> </span><span style="color: #000000">|</span><span style="color: #000000FF">
</span><span style="color: #267F99"><data-lsp lsp='type FooterLocaleIDs =
"footer title" | "footer sendoff"'
>FooterLocaleIDs</data-lsp></span><span style="color: #0000FF">}</span><span style="color:
#A31515"> id`</span><span style="color: #000000">;</span></div><span class='popover-
prefix'> </span><span class='popover'> <div class='arrow'> </div>type AllLocaleIDs =
"welcome_email_id" | "email_heading_id" | "footer_title_id" | "footer_sendoff_id" </span> </code>
<a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAogtgQwJYBsAyB7AxglECSAlgM5QC8UA
</div>
```

For each interpolated position in the template literal, the unions are cross multiplied:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
AllLocaleIDs = & amp; quot; welcome email id& amp; quot; |
"email heading id" | "footer title id" |
"footer_sendoff_id"' > AllLocaleIDs < /data-lsp > </span > < span style="color:
\#000000" = </span><span style="color: \#A31515">`</span><span style="color:
#0000FF">${</span><span style="color: #267F99"><data-lsp lsp='type EmailLocaleIDs =
"welcome email" | "email heading"'
>EmailLocaleIDs</data-lsp></span><span style="color: #000000FF"> </span><span
style="color: #000000">|</span><span style="color: #000000FF"> </span><span style="color:
#267F99"> < data-lsp lsp='type FooterLocaleIDs = & amp;quot;footer_title& amp;quot; |
"footer_sendoff"' > FooterLocaleIDs < /data-lsp > </span > < span style="color:
#0000FF">}</span><span style="color: #A31515">_id`</span><span style="color: #000000">;
</span> </div> < div class='line'> < span style="color: #0000FF"> type < / span> < span style="color: #0000FF"> type < / span style="color: #0000FF"> type < span style="color: #0000FF"> ty
#000000"> </span><span style="color: #267F99"> <data-lsp lsp='type Lang =
"en" | "ja" | "pt" ' > Lang < /data-
lsp></span><span style="color: #000000"> = </span><span style="color: #A31515"> "en"
</span><span style="color: #000000"> | </span><span style="color: #A31515"> "ja"</span>
<span style="color: #000000"> | </span><span style="color: #A31515"> "pt" </span> < span</pre>
style="color: #000000">;</span></div> <div class='line'><span style="color:

style="color: #000000"> = </span><span style="color: #A31515">`</span><span style="color:
#0000FF">${</span><span style="color: #267F99"><data-lsp lsp='type Lang =
"en" | "ja" | "pt" ' > Lang < /data-
lsp></span><span style="color: #0000FF">}</span><span style="color: #A31515">_</span>
<span style="color: #0000FF">${</span><span style="color: #267F99"><data-lsp lsp='type</pre>
AllLocaleIDs = & amp; quot; welcome email id& amp; quot; |
"email heading id" | "footer title id" |
"footer_sendoff_id"' > AllLocaleIDs < /data-lsp > </span > < span style="color:
#0000FF">}</span><span style="color: #A31515">`</span><span style="color: #000000">;
</span></div><span class='popover-prefix'> </span><span class='popover'><div
class='arrow'></div>type LocaleMessageIDs = "en_welcome_email_id" | "en_email_heading_id" |
"en_footer_title_id" | "en_footer_sendoff_id" | "ja_welcome_email_id" | "ja_email_heading_id" |
"ja_footer_title_id" | "ja_footer_sendoff_id" | "pt_welcome_email_id" | "pt_email_heading_id" |
"pt footer title id" | "pt footer sendoff id" </span> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAogtgQwJYBsAyB7AxglECSAlgM5QC8UA
IBQAHoA-EA'>Try</a></div>
```

We generally recommend that people use ahead-of-time generation for large string unions, but this is useful in smaller cases.

String Unions in Types

The power in template literals comes when defining a new string based off an existing string inside a type.

For example, a common pattern in JavaScript is to extend an object based on the fields that it currently has. We'll provide a type definition for a function which adds support for an on function which lets you know when a value has changed:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> < const </span> < span style="color: #000000"> </span> < span style="color: #0070C1"> < data-lsp lsp='const person: any' > person</data-lsp> </span> < span style="color: #000000"> = </span> < span style="color: #795E26"> < data-lsp lsp='function makeWatchedObject(obj: any): any' > makeWatchedObject</data-lsp> </span> < span style="color: #000000"> ({</span> </div> < div class='line'> < span style="color: #001080"> < data-lsp lsp='(property) firstName: string' > firstName</data-lsp>:</span> < span style="color: #000000"></span> < span style="color: #000000"> </span> < span style="color: #000000"> <
```

```
</span><span style="color: #A31515">"Saoirse"</span><span style="color: #000000">,</span>
 </div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(property) lastName: string' >lastName</data-lsp>:</span><span style="color:</pre>
#000000"> </span><span style="color: #A31515"> "Ronan" </span> < span style="color: "A31515" > "Ronan" </span> < span style="color: "A31515" > "Ronan" </span> < span style="color: "A31515" > "Ronan" < span 
#000000">,</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(property) age: number' > age < /data-lsp>: < /span> < span
style="color: #000000"> </span><span style="color: #098658">26</span><span style="color:
#000000">,</span></div><div class='line'><span style="color: #000000">});</span></div>
<div class='line'><span style="color: #001080"> <data-lsp lsp='const person: any'</pre>
>person</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='any' > on < /data-lsp> < /span> < span style="color: #000000"> (< /span>
<span style="color: #A31515">"firstNameChanged"</span><span style="color: #000000">,
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) new Value: any'
>newValue</data-lsp></span><span style="color: #000000">) </span><span style="color:
\#0000FF">=\></span><span style="color: <math>\#000000">\{</span></div><div class='line'><span style='line'><span style='lin
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='var console:
Console' > console < /data-lsp > </span > <span style="color: #000000">.</span > <span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #A31515">`firstName was
changed to </span> < span style="color: #0000FF">${</span> < span style="color: #001080">
<data-lsp lsp='(parameter) newValue: any' > newValue/data-lsp> </span> < span style="color:</pre>
#0000FF">}</span><span style="color: #A31515">!`</span><span style="color: #000000">);
</span></div><div class='line'><span style="color: #000000">});</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEDsHsFECd7XgZwFABMCmBjANgIbxagBmArpD
</div>
```

Notice that on listens on the event "firstNameChanged", not just "firstName", template literals provide a way to handle this sort of string manipulation inside the type system:

```
style="color: #0000FF">${</span><span style="color: #267F99">string</span><span
style="color: #000000FF"> </span><span style="color: #000000">&</span><span style="color:
#000000FF"> </span><span style="color: #0000FF">keyof</span><span style="color:
#000000FF"> </span><span style="color: #267F99"> < data-lsp lsp='(type parameter) Type in
type PropEventSource<Type>' >Type</data-lsp> </span> < span style="color: #0000FF">}
</span><span style="color: #A31515">Changed`</span><span style="color: #000000">,
</span><span style="color: #795E26"><data-lsp lsp='(parameter) callback: (newValue: any) =>
void' > callback < /data-lsp > < /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< /span > < span style="color: #000000" > : (< span style="color: #000
#001080"> < data-lsp lsp='(parameter) newValue: any' > newValue < /data-lsp > </span> < span
style="color: #000000">: </span><span style="color: #267F99">any</span><span style="color:
#000000">) </span><span style="color: #0000FF">=&gt;</span><span style="color: #000000">

Inference with Template Literals

Note how the last examples did not re-use the type of the original value. The callback used an any . Template literal types can infer from substitution positions.

We can make our last example generic to infer from parts of the eventName string to figure out the associated property.

<div class='code-container'> <code> <div class='line'> type <data-lsp lsp='type PropEventSource&lt;Type> = {&#13; on&lt;Key extends string &amp; keyof Type> (eventName: `\${Key}Changed`, callback: (newValue: Type[Key]) => void): void;&#13;}' > PropEventSource</data-lsp> < < > = { </div> <div class='line'> <data-lsp lsp='(method) on&lt;Key extends string &amp; keyof Type> (eventName: `\${Key}Changed`, callback: (newValue: Type[Key]) => void): void' >on</data-lsp <data-lsp lsp='(method) on&lt;Key extends string &amp; keyof Type> (eventName: `\${Key}Changed`, callback: (newValue: Type[Key]) => void): void' >on</data-lsp </pre>

href='https://www.typescriptlang.org/play/#code/C4TwDgpgBACgTgezAUQG4QHbAMoIK5wDGEAPACrounder-by-based

Here we made on into a generic method.

When a user calls with the string "firstNameChanged', TypeScript will try to infer the right type for Key. To do that, it will match Key against the content prior to "Changed" and infer the string "firstName". Once TypeScript figures that out, the on method can fetch the type of firstName on the original object, which is string in this case. Similarly, when called with "ageChanged", TypeScript finds the type for the property age which is number.

Inference can be combined in different ways, often to deconstruct strings, and reconstruct them in different ways.

Intrinsic String Manipulation Types

To help with string manipulation, TypeScript includes a set of types which can be used in string manipulation. These types come built-in to the compiler for performance and can't be found in the .d.ts files included with TypeScript.

Uppercase<StringType>

Converts each character in the string to the uppercase version.

Example

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Greeting = & amp;quot;Hello, world"' > Greeting < /data-lsp > </span > < span style="color:
\#000000" = </span><span style="color: \#A31515">"Hello, world"</span></div><div
class='line'><span style="color: #0000FF">type</span><span style="color: #000000"> </span>

style="color: #0000FF">type <data-lsp lsp='type MainID = &quot;ID-MY_APP&quot;' > MainID</data-lsp> = <data-lsp lsp='type ASCIICacheKey&lt;Str extends string> = `ID-\${Uppercase&lt;Str>}'' > ASCIICacheKey</data-lsp> < > </div> <div class='arrow'> </div> type MainID = "ID-MY_APP" </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBA4gThCwCWA7A5IAvFARACQgBsiB7AGic </div>

Lowercase<StringType>

Converts each character in the string to the lowercase equivalent.

Example

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
Greeting = & amp;quot; Hello, world" '> Greeting < /data-lsp > </span > < span style = "color:
\#000000" = </span><span style="color: \#A31515">"Hello, world"</span></div><div
class='line'><span style="color: #0000FF">type</span><span style="color: #000000"> </span>
<span style="color: #267F99"> < data-lsp lsp='type QuietGreeting = &amp;quot;hello,</pre>
world"' >QuietGreeting</data-lsp></span><span style="color: #000000"> = </span>
<span style="color: #267F99"> < data-lsp lsp='type Lowercase&amp;lt;S extends string> =
intrinsic' >Lowercase</data-lsp></span><span style="color: #000000">&lt;</span><span
style="color: #267F99"> < data-lsp lsp='type Greeting = & amp;quot;Hello, world& amp;quot;'
>Greeting</data-lsp></span><span style="color: #000000">&gt;</span></div><span
class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>type
QuietGreeting = "hello, world" </span> < div class = 'line' > < span style = "color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type ASCIICacheKey&amp;lt;Str extends string> = `id-${Lowercase&amp;lt;Str>}''
>ASCIICacheKey</data-lsp></span><span style="color: #000000">&It;</span><span
style="color: #267F99"> < data-lsp lsp='(type parameter) Str in type ASCIICacheKey&amp;lt;Str
extends string>' > Str < /data-lsp> < /span> < span style="color: #000000"> < /span> < span
style="color: #0000FF"> extends </span> < span style="color: #000000"> </span> < span
style="color: #267F99">string</span><span style="color: #000000">&gt; = </span><span
style="color: #A31515"> id-</span> < span style="color: #0000FF"> ${</span> < span style="color: #0000FF"> ${</span style="color: #0000FF"> ${<span style="color: #0000FF"> ${<s
#267F99"> < data-lsp lsp='type Lowercase&amp;lt;S extends string> = intrinsic'
>Lowercase</data-lsp></span><span style="color: #000000FF">&lt;</span><span style="color:
#267F99"> < data-lsp lsp='(type parameter) Str in type ASCIICacheKey&amp;lt;Str extends string>'
>Str</data-lsp></span><span style="color: #000000FF">&gt;</span><span style="color:
```

```
#0000FF">}</span><span style="color: #A31515">`</span></div><div class='line'> <span style="color: #0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type MainID = &amp;quot;id-my_app&amp;quot;' > MainID </data-lsp> </span><span style="color: #000000"> = </span><span style="color: #267F99"> <data-lsp lsp='type ASCIICacheKey&amp;lt;Str extends string> = `id-${Lowercase&amp;lt;Str>}`' > ASCIICacheKey</data-lsp> </span> <span style="color: #000000"> &lt;</span> <span style="color: #000000"> &lt;</span> <span style="color: #000000"> &gt;</span> </div> <span class='popover-prefix'> </span> <span class='popover'> <div class='arrow'> </div> type MainID = "id-my_app"</span> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBA4gThCwCWA7A5IAvFARACQgBsiB7AGic ExbhoAQQDKAYQCSNq9MkALCAGkIIBReBwoEAB7AEKj0sICyPqpqQgAGyPQAtAAkAN6i4IJyit5wagC+M'. </div>
```

Capitalize<StringType>

Converts the first character in the string to an uppercase equivalent.

Example

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='type</pre>
LowercaseGreeting = & amp;quot; hello, world& amp;quot; '> LowercaseGreeting < /data-lsp>
</span><span style="color: #000000"> = </span><span style="color: #A31515"> "hello, world"
</span><span style="color: #000000">;</span></div><div class='line'><span style="color:
#0000FF">type</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='type Greeting = &amp;quot;Hello, world&amp;quot;' > Greeting < /data-lsp>
</span><span style="color: #000000"> = </span><span style="color: #267F99"> <data-lsp
lsp='type Capitalize<S extends string> = intrinsic' >Capitalize</data-lsp></span><span
style="color: #000000"><</span><span style="color: #267F99"><data-lsp lsp='type
LowercaseGreeting = & amp;quot;hello, world"' > LowercaseGreeting < /data-lsp>
</span><span style="color: #000000">&qt;;</span></div><span class='popover-prefix'>
</span><span class='popover'><div class='arrow'></div>type Greeting = "Hello, world"</span>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAMg9gdwgJwMYEMDOEDiyITACWAdgOZ
</div>
```

Uncapitalize<StringType>

Converts the first character in the string to a lowercase equivalent.

Example

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> type < / span> <data-lsp lsp='type</pre> UppercaseGreeting = & amp; quot; HELLO WORLD& amp; quot; '> UppercaseGreeting < / data-lsp> = "HELLO WORLD";</div><div class='line'>type < data-lsp lsp='type UncomfortableGreeting = & amp;quot;hELLO WORLD& amp;quot;' >UncomfortableGreeting</data-lsp> = < data-lsp lsp='type Uncapitalize&lt;S extends string> = intrinsic' >Uncapitalize</data-lsp>< < data-lsp lsp='type UppercaseGreeting = & amp;quot;HELLO WORLD& amp;quot;' >UppercaseGreeting</data-lsp>>;</div> < div class='arrow'> </div>type UncomfortableGreeting = "hELLO WORLD" </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/C4TwDgpgBAgmkCcDGBDAzhA4giFgEsA7AcygF4oAi/ </div> <details> <summary>Technical details on the intrinsic string manipulation types </summary > The code, as of TypeScript 4.1, for these intrinsic functions uses the JavaScript string runtime functions directly for manipulation and are not locale aware. function applyStringMapping(symbol: Symbol, str: string) { switch (intrinsicTypeKinds.get(symbol.escapedName as string)) { case IntrinsicTypeKind.Uppercase: return str.toUpperCase(); case IntrinsicTypeKind.Lowercase: return str.toLowerCase(); case IntrinsicTypeKind.Capitalize: return str.charAt(0).toUpperCase() + str.slice(1); case IntrinsicTypeKind.Uncapitalize: return str.charAt(0).toLowerCase() + str.slice(1); } return str; } </code> </details>

Classes

<blockquote class='bg-reading'> Background Reading:
 Classes
(MDN) </blockquote>

TypeScript offers full support for the class keyword introduced in ES2015.

As with other JavaScript language features, TypeScript adds type annotations and other syntax to allow you to express relationships between classes and other types.

Class Members

Here's the most basic class - an empty one:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> < < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='class Point' > Point < / data-lsp> < / span> < span style="color: #000000"> {} < / span> < / div> < / code> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEAKD2BLAdgF2gbwL5A'>Try < / a> </div>
```

This class isn't very useful yet, so let's start adding some members.

Fields

A field declaration creates a public writeable property on a class:

<div class='code-container'> <code> <div class='line'> class < <data-lsp lsp='class Point' > Point </data-lsp> { <div > <div class='line'> <data-lsp lsp='(property) Point.x: number' >x</data-lsp> : : </div > <div class='line'> <data-lsp lsp='(property) Point.y: number' >y </data-lsp> : : <div > <div class='line'> ; </div> <div class='line'> </div> <div class='line'> </div> <div class='line'>

```
= </span><span style="color: #0000FF">new </span> <span style="color: #000000"> </span>
<span style="color: #795E26"> <data-lsp lsp='constructor Point(): Point' > Point </data-lsp>
</span> <span style="color: #000000">(); </span> </div> <div class='line'> <span style="color: #000000">.

#001080"> <data-lsp lsp='const pt: Point' > pt </data-lsp> </span> <span style="color: #000000">.

</span> <span style="color: #001080"> <data-lsp lsp='(property) Point.x: number' > x </data-lsp>
</span> <span style="color: #000000"> = </span> <span style="color: #098658">0 </span>
<span style="color: #000000">;</span> </div> <div class='line'> <span style="color: #001080">
<data-lsp lsp='const pt: Point' > pt </data-lsp> </span> <span style="color: #000000">.</span>
<span style="color: #001080"> <data-lsp lsp='(property) Point.y: number' > y </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #098658"> 0 </span> <span style="color: #000000"> ;</span> </span> <span style="color: #000000"> ;</span> </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEGcBcCcEsDG0AKsD2AHApraBPASQDt5p4BDAC
 </div>
```

As with other locations, the type annotation is optional, but will be an implicit any if not specified.

Fields can also have *initializers*; these will run automatically when the class is instantiated:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Point'</pre>
>Point</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)</pre>
Point.x: number' >x</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #098658">0</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) Point.y: number' >y </data-lsp> </span> < span style="color: #000000"> =
</span><span style="color: #098658">0</span><span style="color: #000000">;</span></div>
<div class='line'><span style="color: #000000">}</span></div> <div class='line'><span</pre>
style="color: #0000FF">const</span><span style="color: #000000"> </span><span style="color:
#0070C1"> <data-lsp lsp='const pt: Point' >pt</data-lsp> </span> <span style="color: #000000">
= </span> < span style="color: #0000FF"> new </span> < span style="color: #000000"> </span>
<span style="color: #795E26"> <data-lsp lsp='constructor Point(): Point' > Point < /data-lsp>
</span><span style="color: #000000">();</span></div><div class='line'><span style="color:
#008000">// Prints 0, 0</span></div><div class='line'><span style="color: #001080"><data-lsp
lsp='var console: Console' >console</data-lsp></span><span style="color: #000000">.</span>
<span style="color: #795E26"> <data-lsp lsp='(method) Console.log(...data: any[]): void'</pre>
>log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">`</span><span style="color: #0000FF">${</span><span style="color: #001080">
<data-lsp lsp='const pt: Point' >pt</data-lsp></span><span style="color: #000000FF">.</span>
<span style="color: #001080"> <data-lsp lsp='(property) Point.x: number' >x</data-lsp></span>
<span style="color: #0000FF">}</span><span style="color: #A31515">, </span><span</pre>
style="color: #0000FF">${</span><span style="color: #001080"><data-lsp lsp='const pt: Point'
>pt</data-lsp></span><span style="color: #000000FF">.</span><span style="color: #001080">
```

```
<data-lsp lsp='(property) Point.y: number' >y</data-lsp> </span> <span style="color: #0000FF">}
</span> <span style="color: #A31515">`</span> <span style="color: #000000">);</span> </div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEAKD2BLAdgF2gbwFDWgD2gF5oAGAbh
</div>
```

Just like with const, let, and var, the initializer of a class property will be used to infer its type:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const < / span> < span style="color: #000000"> < / span> < span style="color: #0070C1"> < data-lsp lsp='const pt: Point' > pt</data-lsp> < / span> < span style="color: #000000"> = < / span> < span style="color: #795E26"> < data-lsp lsp='constructor Point(): Point' > Point< / data-lsp> < / span> < span style="color: #795E26"> < data-lsp lsp='constructor Point(): Point' > Point< / data-lsp> < / span> < span style="color: #001080"> < data-lsp lsp='const pt: Point' > pt< / data-lsp> < / span> < span style="color: #001080"> < data-lsp lsp='const pt: Point' > pt< / data-lsp> < / span> < span style="color: #000000"> . < / span> < span style="color: #001080"> < data-lsp lsp='(property) Pointx: number' > x< / data-lsp> < / span> < span style="color: #000000"> : < / span> < span style="color: #31515"> "0" < / span> < span style="color: #000000"> = < / span> < span class="error"> < span> Type 'string' is not assignable to type 'number'. < / span> < span class="error-behind"> Type 'string' is not assignable to type 'number'. < / span> < span class="error-behind"> Type 'string' is not assignable to type 'number'. < / span> < / span> < / span> < / span> < span class="error-behind"> Type 'string' is not assignable to type 'number'. < / span> < / span> < / span> < span class="error-behind"> Type 'string' is not assignable to type 'number'. < / span> < / span> < span style="color: #00000"> (span> < span style="color: #00000"> (span

--strictPropertyInitialization

The strictPropertyInitialization setting controls whether class fields need to be initialized in the constructor.

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> class</span> <<span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='class</pre>
BadGreeter' >BadGreeter
BadGreeter' /span> <span style="color: #000000"> {</span> </div> <div class='line'> <span style="color: #001080"> <data-err> <data-lsp lsp='(property) BadGreeter.name: string' >name</data-lsp> </data-err> 
/data-err> <data-lsp lsp='(property) BadGreeter.name: string' >name
/data-lsp> 
// Span> 
/span> style="color: #267F99"> string
/span> <span style="color: #000000">: </span> <span style="color: #267F99"> string
/span> <span style="color: #000000">; </span> </div> <span class="error"> <span> Property 'name' has no initializer and is not definitely assigned in the constructor.</pan> <span class="line'> <span style="color: #00000"> }
// Span> 
/div> 
/div class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> <span style="color: #FFFFFF; color: #000000"> <span style="color: #FFFFFF; color: #000000"> <span style="color: #FFFFFF; color: #00000"> <span style="color: #FFFFFF; color: #FFFFFF; color: #000000"> <div class='code-container'> <code> <div class='line'> <span style="color: #FFFFFF; color: #00000"> <span style="color: #00000"> <span style="col
```

href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEDiD28AmsBOBTdAXdroG8AoaaAOzAFt0</div>

Note that the field needs to be initialized *in the constructor itself*. TypeScript does not analyze methods you invoke from the constructor to detect initializations, because a derived class might override those methods and fail to initialize the members.

If you intend to definitely initialize a field through means other than the constructor (for example, maybe an external library is filling in part of your class for you), you can use the *definite assignment assertion operator*, !:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> class </span> < <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='class </span> </span> </div> <div <cdiv <cd><cdiv <cd
```

readonly

Fields may be prefixed with the readonly modifier. This prevents assignments to the field outside of the constructor.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
Greeter' > Greeter < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color:
#0000FF">readonly</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(property) Greeter.name: string' > name < /data-lsp > </span> < span
style="color: #000000">: </span><span style="color: #267F99">string</span><span
style="color: #000000"> = </span><span style="color: #A31515"> "world" </span> < span

<span style="color: #000000"> = </span><span style="color: #A31515"> "not ok"</span><span</pre>
style="color: #000000">;</span></div><span class="error"><span>Cannot assign to 'name'
because it is a read-only property.</span><span class="code">2540</span></span><span
class="error-behind">Cannot assign to 'name' because it is a read-only property.</span><div
class='line'><span style="color: #000000"> }</span></div><div class='line'><span style="color:
#000000">}</span></div><div class='line'><span style="color: #0000FF">const</span><span
style="color: #000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const g: Greeter'
>q</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#0000FF">new</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='constructor Greeter(otherName?: string | undefined): Greeter' > Greeter < /data-lsp>
</span><span style="color: #000000">();</span></div><div class='line'><span style="color:
#001080"> <data-lsp lsp='const g: Greeter' > g </data-lsp> </span> <span style="color:
#000000">.</span><span style="color: #001080"><data-err><data-lsp lsp='(property)
```

Greeter.name: string' >name</data-lsp></data-err> = "also not ok"; </div> Cannot assign to 'name' because it is a read-only property.2540 Cannot assign to 'name' because it is a read-only property.</code> Try </div>

Constructors

Class constructors are very similar to functions. You can add parameters with type annotations, default values, and overloads:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> <data-lsp lsp='class Point'</pre> >Point</data-lsp> {</div><div class='line'> <data-lsp lsp='(property)</pre> Point.x: number' >x</data-lsp>: number;</div><div class='line'> <data-lsp lsp='(property) Point.y: number' >y </data-lsp> < span style="color: #000000">: number;</div> <div class='line'> // Normal signature with defaults</div><div class='line'> constructor (<data-lsp lsp='(parameter) x: number' >x </data-lsp> = 0, < data-lsp</pre> lsp='(parameter) y: number' >y</data-lsp> = 0) {</div><div</pre> class='line'> this .<data-lsp lsp='(property)</pre> Point.x: number' >x</data-lsp> = < data-lsp lsp='(parameter) x: number' > x < /data-lsp > < span style="color: #000000">;</div><div class='line'> this. <data-lsp lsp='(property) Point.y: number' >y </data-lsp>

```
<span style="color: #000000"> = </span><span style="color: #001080"> < data-lsp</pre>
lsp='(parameter) y: number' >y</data-lsp></span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000"> }</span></div><div class='line'><span
style="color: #000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEAKD2BLAdgF2gbwFDWgDwC5pkBXAW
#000000"> < div class='code-container' > < code > < div class='line' > < span style="color:
#0000FF">class</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='class Point' > Point</data-lsp> </span> < span style="color: #000000"> {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #008000">//
Overloads</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #0000FF">constructor</span><span style="color: #000000">(</span><span
style="color: #001080"> < data-lsp lsp='(parameter) x: number' > x < /data-lsp > </span> < span
style="color: #000000">: </span><span style="color: #267F99">number</span><span
style="color: #000000">, </span><span style="color: #001080"> < data-lsp lsp='(parameter) y:
string' >y</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #0000FF">constructor</span><span
style="color: #000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) s:
string' >s</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">);</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #0000FF">constructor</span><span
style="color: #000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) xs:
any' >xs</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">any</span><span style="color: #000000">, </span><span style="color: #001080">
<data-lsp lsp='(parameter) y: any' >y</data-lsp></span><span style="color: #000000">?:
</span><span style="color: #267F99">any</span><span style="color: #000000">) {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #008000">//
TBD</span></div><div class='line'><span style="color: #000000"> }</span></div><div
class='line'><span style="color: #000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEAKD2BLAdgF2gbwFDWgej2gHkA3AUw
</div>
```

There are just a few differences between class constructor signatures and function signatures:

- Constructors can't have type parameters these belong on the outer class declaration, which we'll learn about later
- Constructors can't have return type annotations the class instance type is always what's returned

Super Calls

Just as in JavaScript, if you have a base class, you'll need to call super(); in your constructor body before using any this. members:

 < div</pre> class='code-container'> <code> <div class='line'> class <data-lsp lsp='class Base'</pre> >Base</data-lsp> {</div><div class='line'> <data-lsp lsp='(property)</pre> Base.k: number' >k</data-lsp> = 4;</div><div class='line'>}</div> <div class='line'>class <data-lsp lsp='class Derived' > Derived</data-lsp> extends <data-lsp lsp='class Base' > Base < /data-lsp > <span</pre> style="color: #000000"> {</div><div class='line'> constructor() {</div><div class='line'> // Prints a wrong value in ES5; throws exception in ES6</div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. <data-lsp lsp='(method) Console.log(...data: any[]): void'</pre> >log</data-lsp>(<data-err>this</data-err>. <data-lsp lsp='(property) Base.k: number' >k</data-lsp>);</div>'super' must be called before accessing 'this' in the constructor of a derived class.17009 'super' must be called before accessing 'this' in the constructor of a derived class.<div class='line'> super();</div><div class='line'> }</div><div class='line'>}</div></code>Try</div>

Forgetting to call super is an easy mistake to make in JavaScript, but TypeScript will tell you when it's necessary.

Methods

<blockquote class='bg-reading'> Background Reading:
 <a
href='https://developer.mozilla.org/en-</pre>

US/docs/Web/JavaScript/Reference/Functions/Method_definitions'>Method definitions
 </blockguote>

A function property on a class is called a *method*. Methods can use all the same type annotations as functions and constructors:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> <data-lsp lsp='class Point'</pre> >Point</data-lsp> {</div><div class='line'> <data-lsp lsp='(property)</pre> Point.x: number' >x</data-lsp> = 10;</div><div class='line'> <data-lsp lsp='(property) Point.y: number' >y </data-lsp> < span style="color: #000000"> = < span style="color: #098658">10 < /span> < span style="color: #000000">; < /span> </div> <div class='line'> <data-lsp lsp='(method) Point.scale(n: number): void' >scale</data-lsp>(<data-lsp lsp='(parameter) n: number' >n</data-lsp>: number): void {</div><div class='line'> this.<data-lsp lsp='(property) Point.x: number' x</data-lsp<< span style="color: #000000"> *= < span style="color: #001080"> *= *= </<data-lsp lsp='(parameter) n: number' >n</data-lsp>; </div><div class='line'> this. <data-lsp lsp='(property) Point.y: number' >y</data-lsp> *= < span style="color: #001080"> < data-lsp lsp='(parameter) n: number' > n < /data-lsp> ;</div><div class='line'> }</div><div class='line'>}</div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEAKD2BLAdgF2gbwFDWgD2gF5oBGABg </div>

Other than the standard type annotations, TypeScript doesn't add anything else new to methods.

Note that inside a method body, it is still mandatory to access fields and other methods via this.. An unqualified name in a method body will always refer to something in the enclosing scope:

< div class='code-container'> < code> < div class='line'> < span style="color: #00000FF"> let < / span> < span style="color: #000000"> < / span> < span style="color: #001080"> < data-lsp lsp='let x: number'</pre>

```
>x</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000"> = </span><span style="color:
#098658">0</span><span style="color: #000000">;</span></div> <div class='line'><span
style="color: #0000FF">class</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='class C' > C < /data-lsp> < /span> < span style="color: #000000">
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#001080"> <data-lsp lsp='(property) C.x: string' >x </data-lsp> </span> <span style="color:
#000000">: </span> <span style="color: #267F99"> string </span> < span style="color: #000000">
= </span> < span style="color: #A31515"> "hello" </span> < span style="color: #000000">; </span>
</div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #795E26">
<data-lsp lsp='(method) C.m(): void' >m</data-lsp></span><span style="color: #000000">()
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#008000">// This is trying to modify 'x' from line 1, not the class property</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">
<data-err> <data-lsp lsp='let x: number' >x</data-lsp> </data-err> </span> <span style="color:</pre>
\#000000" = </span><span style="color: \#A31515">"world"</span><span style="color:
#000000">;</span></div><span class="error"><span>Type 'string' is not assignable to type
'number'.</span><span class="code">2322</span></span><span class="error-behind">Type
'string' is not assignable to type 'number'.</span><div class='line'><span style="color:
#000000"> }</span></div><div class='line'><span style="color: #000000">}</span></div>
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2qZwFyqEwGY1oFABtlAXUAD1QDsBX
</div>
```

Getters / Setters

Classes can also have accessors:

Note that a field-backed get/set pair with no extra logic is very rarely useful in JavaScript. It's fine to expose public fields if you don't need to add additional logic during the get/set operations.

TypeScript has some special inference rules for accessors:

- If no set exists, the property is automatically readonly
- The type of the setter parameter is inferred from the return type of the getter
- If the setter parameter has a type annotation, it must match the return type of the getter
- Getters and setters must have the same <u>Member Visibility</u>

It is not possible to have accessors with different types for getting and setting.

If you have a getter without a setter, the field is automatically readonly

Index Signatures

Classes can declare index signatures; these work the same as <u>Index Signatures for other object types</u>:

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
 < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='class
 MyClass' > MyClass < / data-lsp> < / span> < span style="color: #000000"> { < / span> < / div > < div
 class='line'> < span style="color: #000000"> [< / span> < span style="color: #001080"> < data-lsp
 lsp='(parameter) s: string' > s < / data-lsp> < / span> < span style="color: #000000"> : < / span> < span
 style="color: #267F99"> string < / span> < span style="color: #000000">]: < / span> < span
 style="color: #267F99"> boolean < / span> < span style="color: #000000"> | ((< / span> < span style="color: #001080"> < data-lsp lsp='(parameter) s: string' > s < / data-lsp> < / span> < span
 style="color: #001080"> < data-lsp lsp='(parameter) s: string' > s < / data-lsp> < / span> < span</pre>

```
style="color: #000000">: </span><span style="color: #267F99">string</span><span
style="color: #000000">) </span><span style="color: #0000FF">=&gt;</span><span
style="color: #000000"> </span><span style="color: #267F99">boolean</span><span
style="color: #000000">);</span></div> <div class='line'><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='(method) MyClass.check(s: string): boolean'
>check</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> <data-lsp lsp='(parameter) s: string' >s </data-lsp> </span> <span style="color:
#000000">: </span><span style="color: #267F99">string</span><span style="color: #267F99">string</span style="color: #267F999">string</span style="color: #267F9999</span style="color: #267F9999</span style="color: #267F9999</span style="color: #267F9999</span style="color: #267F9999</span style="color: #267F9999</span style="color: #267F999</span style="color: #267F999</span st
#000000">) {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #AF00DB">return</span><span style="color: #000000"> </span><span
style="color: #0000FF">this</span><span style="color: #000000">[</span><span style="color:
#001080"> < data-lsp lsp='(parameter) s: string' > s < /data-lsp > < /span > < span style="color:
#000000">] </span> <span style="color: #AF00DB">as </span> <span style="color: #000000">
</span><span style="color: #267F99">boolean</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000"> }</span></div><div class='line'><span
style="color: #000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyCeBhcVoG8BQ1oG0IC5oIAXAJwEsA7
</div>
```

Because the index signature type needs to also capture the types of methods, it's not easy to usefully use these types. Generally it's better to store indexed data in another place instead of on the class instance itself.

Class Heritage

Like other languages with object-oriented features, classes in JavaScript can inherit from base classes.

implements Clauses

You can use an implements clause to check that a class satisfies a particular interface. An error will be issued if a class fails to correctly implement it:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < span style="color: #000000"> < span style="color: #267F99"> < data-lsp lsp='interface Pingable' > Pingable < / data-lsp> < / span> < span style="color: #000000"> { < / div> < div class='line'> < span style="color: #000000"> < / span> < span style="color: #795E26"> < data-lsp lsp='(method) Pingable.ping(): void' > ping < / data-lsp> < / span> < span style="color: #000000"> (): < span style="color: #000000"> ; < / span> < / div> < div class='line'> < span style="color: #000000"> ; < / span> < / div> < div class='line'> < span style="color: #000000"> < / span> < span style="color: #000000"> < span s

```
#267F99"> < data-lsp lsp='class Sonar' > Sonar < /data-lsp> < /span> < span style="color: #000000">
</span><span style="color: #0000FF">implements</span><span style="color: #000000">
</span><span style="color: #267F99"><data-lsp lsp='interface Pingable' > Pingable < /data-lsp>
</span><span style="color: #000000"> {</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #795E26"> <data-lsp lsp='(method) Sonar.ping(): void'
>ping</data-lsp></span><span style="color: #000000">() {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='var</pre>
console: Console' >console</data-lsp></span><span style="color: #000000">.</span><span
style="color: #795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp>
</span><span style="color: #000000">(</span><span style="color: #A31515">"ping!"</span>
<span style="color: #000000">);</span></div><div class='line'><span style="color: #000000">
}</span></div><div class='line'><span style="color: #000000">}</span></div> <div</pre>
class='line'><span style="color: #0000FF">class</span><span style="color: #000000"> </span>

lsp='(method) Console.log(...data: any[]): void' >log</data-lsp> </span> < span style="color:</pre>
#000000">(</span><span style="color: #A31515">"pong!"</span><span style="color:
#000000">);</span></div><div class='line'><span style="color: #000000"> }</span></div>
<div class='line'><span style="color: #000000">}</span></div></code><a class='playground-
link'
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwBY0AYBQBLAOwBcYAzAQ\IcNDdevKjsRwOAOjZxGggBEAtYAhIHCcryKisqq6qAAQhRsbAbGpubElkysHM72fDoBTi6u7oSePn4BwcXhl</div>

Classes may also implement multiple interfaces, e.g. class C implements A, B { .

Cautions

It's important to understand that an implements clause is only a check that the class can be treated as the interface type. It doesn't change the type of the class or its methods *at all*. A common source of error is to assume that an implements clause will change the class type - it doesn't!

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> interface < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface</pre>
Checkable' > Checkable < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) Checkable.check(name: string): boolean' >check</data-lsp></span><span
style="color: #000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter)
name: string' > name < /data-lsp > </span > <span style="color: #000000">: </span > <span
style="color: #267F99">string</span><span style="color: #000000">): </span><span
style="color: #267F99">boolean</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000">}</span></div> <div class='line'><span style="color:
#0000FF">class</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='class NameChecker' > NameChecker < /data-lsp > </span > < span style="color:</pre>
#000000"> </span><span style="color: #0000FF">implements</span><span style="color:
#000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface Checkable'
>Checkable</data-lsp></span><span style="color: #000000"> {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) NameChecker.check(s: any): boolean' > check < /data-lsp > </span > < span
style="color: #000000">(</span><span style="color: #001080"><data-err><data-lsp
lsp='(parameter) s: any' >s</data-lsp></data-err></span><span style="color: #000000">)
{</span></div><span class="error"><span>Parameter 's' implicitly has an 'any' type.</span>
<span class="code">7006</span></span><span class="error-behind">Parameter 's' implicitly
has an 'any' type.</span><div class='line'><span style="color: #000000"> </span><span
style="color: #008000">// Notice no error here</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #AF00DB">return</span><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) s:
any' >s</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='any' style='border-bottom: solid 2px lightgrey;' > toLowercse < /data-lsp >
<span> <span style="color: #000000">() === </span> <span style="color: #A31515">"ok"
</span><span style="color: #000000">;</span></div><span class='popover-prefix'> </span>
<span class='popover'> < div class='arrow'> </div>any </span> < div class='line'> < span</pre>
style="color: #000000"> }</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygOwAYMDYBQBLAOwBcYAzA(
</div>
```

In this example, we perhaps expected that s's type would be influenced by the name: string parameter of check. It is not - implements clauses don't change how the class body is checked or its type inferred.

Similarly, implementing an interface with an optional property doesn't create that property:

 < div class='code-container' > < code > < div class='line' > < span style="color: #0000FF" > interface < / span >

```
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='interface A'</pre>
>A</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property) A.x:
number' >x</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)</pre>
A.y?: number | undefined' >y</data-lsp></span><span style="color: #000000">?: </span><span
style="color: #267F99">number</span><span style="color: #000000">;</span></div><div

extends Clauses

Classes may extend from a base class. A derived class has all the properties and methods of its base class, and also define additional members.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
Animal' > Animal < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) Animal.move(): void' >move</data-lsp></span><span style="color: #000000">()
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:

Overriding Methods

<blockquote class='bg-reading'> Background Reading:
 super keyword (MDN)

</blockquote>

A derived class can also override a base class field or property. You can use the super. syntax to access base class methods. Note that because JavaScript classes are a simple lookup object, there is no notion of a "super field".

TypeScript enforces that a derived class is always a subtype of its base class.

For example, here's a legal way to override a method:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> <data-lsp lsp='class Base'</pre> >Base</data-lsp> {</div><div class='line'> <data-lsp lsp='(method)</pre> Base.greet(): void' > greet < /data-lsp > < span style = "color: #000000" > () { < /div > <div class='line'> <data-</pre> lsp lsp='var console: Console' > console</data-lsp>. <data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>("Hello, world!");</div><div class='line'> }</div><div class='line'>}</div> <div class='line'>class <data-lsp lsp='class Derived' > Derived < /data-lsp > < span style = "color: #000000" > < span style = "color: #0000FF">extends <span style="color:

```
#267F99"> <data-lsp lsp='class Base' > Base </data-lsp> </span> < span style="color: #000000">
{</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='(method) Derived.greet(name?: string | undefined): void' > greet < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) name: string | undefined' > name < /data-lsp > </span > < span style="color:

class='playground-link'
```

href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCkFNoG8BQ1oHMBOCEBcAKAShXQ2r </div>

It's important that a derived class follow its base class contract. Remember that it's very common (and always legal!) to refer to a derived class instance through a base class reference:

< div class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Alias the derived instance through a base class reference < / span> < / div> < div class='line'> < span style="color: #00000FF"> const < / span> < span style="color: #000000"> < / span> < span style="color: #0070C1"> < data-lsp lsp='const b: Base' > b < / data-lsp> < / span> < span style="color: #000000"> : < / span> < span style="color: #000000"> : < / span> < span style="color: #000000"> = < / span> < span style="color: #001080"> < data-lsp lsp='const d: Base' > d < / data-lsp> < / span> < span style="color: #000000"> ; < / span> < / div> < div class='line'> < span style="color: #008000"> // No problem < / span> < / div < div class='line'> < span style="color: #001080"> < data-lsp lsp='const b: Base' > b < / data-lsp> < / span> < span style="color: #000000"> . < / spa

What if Derived didn't follow Base 's contract?

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> <data-lsp lsp='class Base'</pre> >Base</data-lsp> {</div><div class='line'> <data-lsp lsp='(method)</pre> Base.greet(): void' > greet < /data-lsp > < span style = "color: #000000" > () { < /div > <div class='line'> <data-</pre> lsp lsp='var console: Console' > console</data-lsp>. <data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>("Hello, world!");</div><div class='line'> }</div><div class='line'>}</div> <div class='line'>class <data-lsp lsp='class Derived' > Derived < /data-lsp > < span style = "color: #000000" > < span style = "color: #0000FF">extends <data-lsp lsp='class Base' > Base </data-lsp> < span style="color: #000000"> {</div><div class='line'> // Make this parameter required</div><div class='line'> <data-err> <data-lsp lsp='(method) Derived.greet(name: string): void' > greet < /data-lsp > < /data-err > < /span > < span style="color:

```
#000000">(</span><span style="color: #001080"> < data-lsp lsp='(parameter) name: string'
>name</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">) {</span></div><span class="error">
<span>Property 'greet' in type 'Derived' is not assignable to the same property in base type 'Base'.

#795E26"> < data-lsp lsp='(method) String.toUpperCase(): string' > toUpperCase < /data-lsp>
</span><span style="color: #000000FF">()</span><span style="color: #0000FF">}</span>
<span style="color: #A31515">`</span><span style="color: #000000">);</span></div><div</pre>
class='line'><span style="color: #000000"> }</span></div><div class='line'><span style="color:
#000000">}</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwBYCMA2AUAMYA2Ahoog/
</div>
```

If we compiled this code despite the error, this sample would then crash:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const < / span> < span style="color: #000000"> < / span> < span style="color: #0070C1"> < data-lsp lsp='const b: Base' > b < / data-lsp> < / span> < span style="color: #000000"> : < / span> < span style="color: #000000"> = < / span> < span style="color: #000000"> < / span> < span style="color: #795E26"> < data-lsp lsp='constructor Derived(): Derived' > Derived < / data-lsp> < / span> < span style="color: #000000"> // Crashes because "name" will be undefined < / span> < / div> < div class='line'> < span style="color: #001080"> < data-lsp lsp='const b: Base' > b < / data-lsp > < / span> < span style="color: #000000"> . < / span> < span style="color: #000000"> . < / span> < span style="color: #000000"> . < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < / span> < span style="color: #000000"> (); < / span> < span style="
```

Initialization Order

The order that JavaScript classes initialize can be surprising in some cases. Let's consider this code:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Base'</pre>
>Base</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)</pre>
Base.name: string' > name < /data-lsp > </span > <span style="color: #000000"> = </span > <span
style="color: #A31515">"base"</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> </span><span style="color:
#0000FF">constructor</span><span style="color: #000000">() {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='var console: Console' >console</data-lsp></span><span style="color: #000000">.</span>
<span style="color: #795E26"> <data-lsp lsp='(method) Console.log(...data: any[]): void'</pre>
>log</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515">"My name is "</span><span style="color: #000000"> + </span><span style="color:
#0000FF">this</span><span style="color: #000000">.</span><span style="color: #001080">
<data-lsp lsp='(property) Base.name: string' > name</data-lsp> </span> < span style="color:</pre>
#000000">);</span></div><div class='line'><span style="color: #000000"> }</span></div>
<div class='line'><span style="color: #000000">}</span></div> <div class='line'><span</pre>
style="color: #0000FF">class</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='class Derived' > Derived < /data-lsp > </span> < span style="color:
#000000"> </span><span style="color: #0000FF">extends</span><span style="color:
#000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Base' > Base </data-lsp>
</span><span style="color: #000000"> {</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='(property) Derived.name:
string' >name</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#A31515">"derived"</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000">}</span></div> <div class='line'><span style="color:</pre>
#008000">// Prints "base", not "derived"</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const d: Derived' >d</data-lsp></span><span style="color: #000000"> =
</span><span style="color: #0000FF">new</span><span style="color: #000000"> </span>
<span style="color: #795E26"> <data-lsp lsp='constructor Derived(): Derived' > Derived </data-</pre>
lsp></span><span style="color: #000000">();</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCkFNoG8BQ1oDswFskF5oAiAl0SIG51
</div>
```

What happened here?

The order of class initialization, as defined by JavaScript, is:

- The base class fields are initialized
- The base class constructor runs
- The derived class fields are initialized

• The derived class constructor runs

This means that the base class constructor saw its own value for name during its own constructor, because the derived class field initializations hadn't run yet.

Inheriting Built-in Types

Note: If you don't plan to inherit from built-in types like Array, Error, Map, etc., you may skip this section

In ES2015, constructors which return an object implicitly substitute the value of this for any callers of super(...) . It is necessary for generated constructor code to capture any potential return value of super(...) and replace it with this .

As a result, subclassing Error, Array, and others may no longer work as expected. This is due to the fact that constructor functions for Error, Array, and the like use ECMAScript 6's new.target to adjust the prototype chain; however, there is no way to ensure a value for new.target when invoking a constructor in ECMAScript 5. Other downlevel compilers generally have the same limitation by default.

For a subclass like the following:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
MsgError' > MsgError < /data-lsp > </span > <span style="color: #000000" > </span > <span
style="color: #0000FF"> extends </span> < span style="color: #000000"> </span> < span
style="color: #267F99"> < data-lsp lsp='var Error: ErrorConstructor' > Error < /data-lsp > < /span>
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #0000FF">constructor</span><span style="color: #000000">
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) m: string' > m < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">string</span>
<span style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #0000FF">super</span><span style="color: #000000">(</span>
<span style="color: #001080"> <data-lsp lsp='(parameter) m: string' > m </data-lsp> </span>
<span style="color: #000000">);</span></div><div class='line'><span style="color: #000000">
}</span></div><div class='line'><span style="color: #000000"> </span><span style="color:</pre>
#795E26"> < data-lsp lsp='(method) MsgError.sayHello(): string' > sayHello < /data-lsp > < /span>
<span style="color: #000000">() {</span></div><div class='line'><span style="color:</pre>
#000000"> </span><span style="color: #AF00DB">return</span><span style="color:
#000000"> </span> <span style="color: #A31515"> "hello " </span> <span style="color:
#000000"> + </span><span style="color: #0000FF">this</span><span style="color: #000000">.
```

```
</span> <span style="color: #001080"> <data-lsp lsp='(property) Error.message: string'
>message</data-lsp> </span> <span style="color: #000000">;</span> </div> <div class='line'>
<span style="color: #000000"> } </span> </div> <div class='line'> <span style="color: #000000">}
</span> </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyEHMCiAnFB7F0CmAPALtgHYAmMqG
 </div>
```

you may find that:

- methods may be undefined on objects returned by constructing these subclasses, so calling sayHello will result in an error.
- instanceof will be broken between instances of the subclass and their instances, so (new MsgError()) instanceof MsgError will return false.

As a recommendation, you can manually adjust the prototype immediately after any super (. . .) calls.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
MsgError' > MsgError < /data-lsp > </span > <span style="color: #000000" > </span > <span
style="color: #0000FF">extends</span><span style="color: #000000"> </span><span

style="color: #001080"> < data-lsp lsp='(property) MsgError.prototype: MsgError'
>prototype</data-lsp></span><span style="color: #000000">);</span></div><div class='line'>
<span style="color: #000000"> }</span></div> <div class='line'><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='(method) MsgError.sayHello(): string'
```

```
>sayHello</data-lsp></span><span style="color: #000000">() {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #AF00DB">return</span><span
style="color: #000000"> </span><span style="color: #A31515">"hello "</span><span
style="color: #000000"> + </span><span style="color: #0000FF">this</span><span
style="color: #000000"> + </span><span style="color: #001080"> <data-lsp lsp='(property)
Error.message: string' >message</data-lsp></span><span style="color: #000000">;</span>
</div><div class='line'> <span style="color: #000000"> }</span> </div> <div class='line'> <span
style="color: #000000"> }</span> </div> <div class='line'> <span
style="color: #000000"> }</span> </div> <dode> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyEHMCiAnFB7F0CmAPALtgHYAmMqG
</div>
```

However, any subclass of MsgError will have to manually set the prototype as well. For runtimes that don't support object.setPrototype0f, you may instead be able to use object.setPrototype0f, you may instead be able to use object.setPrototype0f.

Unfortunately, these workarounds will not work on Internet Explorer 10 and prior. One can manually copy methods from the prototype onto the instance itself (i.e. MsgError.prototype onto this), but the prototype chain itself cannot be fixed.

Member Visibility

You can use TypeScript to control whether certain methods or properties are visible to code outside the class.

public

The default visibility of class members is public . A public member can be accessed by anywhere:

style="color: #000000"> <data-lsp lsp='const g: Greeter' >g</data-lsp> = <data-lsp lsp='constructor Greeter(): Greeter' >Greeter </data-lsp <data-lsp lsp='constructor Greeter(): Greeter' >Greeter </data-lsp> <data-lsp lsp='const g: Greeter' >g</data-lsp> . . <data-lsp lsp='(method) Greeter.greet(): void' > greet </data-lsp> (); </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEDiBOBTRAXR9oG8BQ1oAcBXAIxAEthoB: </div>

Because public is already the default visibility modifier, you don't ever *need* to write it on a class member, but might choose to do so for style/readability reasons.

protected

protected members are only visible to subclasses of the class they're declared in.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
Greeter' > Greeter < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color:

```

Exposure of protected members

Derived classes need to follow their base class contracts, but may choose to expose a subtype of base class with more capabilities. This includes making protected members public:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Base'</pre>
>Base</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #0000FF">protected</span><span</pre>
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property) Base.m:
number' >m</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#098658">10</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #000000">}</span></div><div class='line'><span style="color:
#0000FF">class</span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='class Derived' > Derived</data-lsp></span><span style="color: #000000">
</span><span style="color: #0000FF">extends</span><span style="color: #000000"> </span>
<span style="color: #267F99"> < data-lsp lsp='class Base' > Base < /data-lsp > </span > < span</pre>
style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #008000">// No modifier, so default is &apos;public&apos;</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(property) Derived.m: number' > m < /data-lsp > </span > < span style="color:
#000000"> = </span><span style="color: #098658">15</span><span style="color: #000000">;
</span></div><div class='line'><span style="color: #000000">}</span></div><div
class='line'><span style="color: #0000FF">const</span><span style="color: #000000"> </span>
<span style="color: #0070C1"> < data-lsp lsp='const d: Derived' > d < /data-lsp > </span> < span</pre>
style="color: #000000"> = </span><span style="color: #0000FF">new</span><span
style="color: #000000"> </span><span style="color: #795E26"> < data-lsp lsp='constructor
Derived(): Derived' > Derived < /data-lsp > </span > < span style="color: #000000" > (); </span > < /div >
<div class='line'><span style="color: #001080"> <data-lsp lsp='var console: Console'</pre>
>console</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span>
<span style="color: #000000">(</span><span style="color: #001080"> < data-lsp lsp='const d:</pre>
#001080"> < data-lsp lsp='(property) Derived.m: number' > m < /data-lsp > </span> < span
style="color: #000000">); </span><span style="color: #008000">// OK</span></div></code>
<a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCkFNoG8BQ1oAcBOB7ALgsIQCbQC2(
</div>
```

Note that <code>Derived</code> was already able to freely read and write <code>m</code>, so this doesn't meaningfully alter the "security" of this situation. The main thing to note here is that in the derived class, we need to be careful to repeat the <code>protected</code> modifier if this exposure isn't intentional.

Cross-hierarchy protected access

Different OOP languages disagree about whether it's legal to access a protected member through a base class reference:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Base'</pre>
>Base</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #0000FF">protected</span><span</pre>
style="color: #000000"> </span><span style="color: #001080"> < data-lsp lsp='(property) Base.x:
number' >x</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000"> = </span><span style="color:
#098658">1</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #000000">}</span></div><div class='line'><span style="color:
#0000FF">class</span><span style="color: #000000"> </span><span style="color: #267F99">

#000000">.<data-err> <data-lsp lsp='(property) Base.x: number' >x</data-lsp> </data-err> = = ; </div> Property 'x' is protected and only accessible through an instance of class 'Derived2'. This is an instance of class 'Base'. 2446 Property 'x' is protected and only accessible through an instance of class 'Derived2'. This is an instance of class 'Base'. <div class='line'> } </div> <div class='line'> } </div> </rode> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwBYMDYBQBjAGwENFFQAP

Java, for example, considers this to be legal. On the other hand, C# and C++ chose that this code should be illegal.

TypeScript sides with C# and C++ here, because accessing x in Derived2 should only be legal from Derived2 's subclasses, and Derived1 isn't one of them. Moreover, if accessing x through a Derived2 reference is illegal (which it certainly should be!), then accessing it through a base class reference should never improve the situation.

See also Why Can't I Access A Protected Member From A Derived Class? which explains more of C#'s reasoning.

private

</div>

private is like protected, but doesn't allow access to the member even from subclasses:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> <data-lsp lsp='class Base'</pre> >Base</data-lsp> {</div><div class='line'> private < span</pre> style="color: #000000"> <data-lsp lsp='(property) Base.x: number' >x</data-lsp> = 0;</div><div class='line'>}</div><div class='line'>const <data-lsp lsp='const b: Base' >b</data-lsp> = new <span</pre> style="color: #795E26"> < data-lsp lsp='constructor Base(): Base' > Base < /data-lsp > < span style="color: #000000">();</div><div class='line'>// Can't access from outside the class </div> < div class = 'line' > < span style = "color: #001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > < span style="color:

class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBGAUAMYA2AhoogA
</div>
```

Because private members aren't visible to derived classes, a derived class can't increase its visibility:

< div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
 < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='class Base'
 >Base</data-lsp> < / span> < span style="color: #000000"> { < / span> < / div> < div class='line'>

</div>
```

Cross-instance private access

Different OOP languages disagree about whether different instances of the same class may access each others' private members. While languages like Java, C#, C++, Swift, and PHP allow this, Ruby does not.

TypeScript does allow cross-instance private access:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class A'</pre>
>A</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #0000FF"> private </span> < span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property) A.x:
number' >x</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#098658">10</span><span style="color: #000000">;</span></div> <div class='line'><span
style="color: #000000"> </span><span style="color: #0000FF">public</span><span
style="color: #000000"> </span><span style="color: #795E26"> < data-lsp lsp='(method)
A.sameAs(other: A): boolean' >sameAs</data-lsp></span><span style="color: #000000">
(</span><span style="color: #001080"><data-lsp lsp='(parameter) other: A' >other</data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99"> < data-lsp
lsp='class A' >A</data-lsp></span><span style="color: #000000">) {</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #008000">// No
error</span></div><div><div><div><span style="color: #000000"> </span><span style="color:
```

```
#AF00DB">return</span><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) other: A' >other</data-lsp></span><span style="color: #000000">.</span><span style="color: #001080"> <data-lsp lsp='(property) A.x: number' >x</data-lsp></span><span style="color: #000000"> === </span><span style="color: #001080"> === </span><span style="color: #001080"> <data-lsp></span><span style="color: #001080"> <data-lsp lsp='(property) A.x: number' >x</data-lsp></span><span style="color: #000000">;</span></div><div class='line'> <span style="color: #000000"> }</span></div> <div class='line'> <span style="color: #000000"> }</span></div> <div class='playground-link' href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECC0G8BQ1oAcBOBLAbmALgKbQAe0Av</div>
```

Caveats

Like other aspects of TypeScript's type system, private and protected are only enforced during type checking. This means that JavaScript runtime constructs like in or simple property lookup can still access a private or protected member:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
MySafe' > MySafe < /data-lsp > </span > < span style = "color: #000000" > { </span > < /div > < div
class='line'> < span style="color: #000000"> </span> < span style="color:
#0000FF">private</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(property) MySafe.secretKey: number' > secretKey < /data-lsp > < /span>
<span style="color: #000000"> = </span><span style="color: #098658">12345</span><span
style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyCeBIMAzAptA3gKGtADgE4CWAbmA(
<div class="language-id">js</div><div class='code-container'><code><div class='line'><span
style="color: #008000">// In a JavaScript file...</span></div><div class='line'><span
style="color: #0000FF">const</span><span style="color: #000000"> </span><span style="color:
\#0070C1">s</span><span style="color: \#000000"> = </span><span style="color:
#0000FF">new </span> < span style="color: #000000"> </span style="color: #0000000"> </span style="color: #000000"> </span style="color: #0000000"> </span style="color: #000000"> </span style="color: #0000000"> </span style="color: #0000000"> </span style="color: #0000000"> </span style="color: #00000000"> </span style="color: #000000000"> </span style="color
#795E26">MySafe</span><span style="color: #000000">();</span></div><div class='line'>
<span style="color: #008000">// Will print 12345</span></div><div class='line'><span</pre>
style="color: #001080">console</span><span style="color: #000000">.</span><span
style="color: #795E26">log</span><span style="color: #000000">(</span><span style="color:
#001080">s</span><span style="color: #000000">.</span><span style="color:
#001080">secretKey</span><span style="color: #000000">);</span></div></code></div>
```

If you need to protect values in your class from malicious actors, you should use mechanisms that offer hard runtime privacy, such as closures, weak maps, or <u>private fields</u>.

Static Members

Static Members (MDN)

<br/

Classes may have static members. These members aren't associated with a particular instance of the class. They can be accessed through the class constructor object itself:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> <data-lsp lsp='class</pre> MyClass' >MyClass</data-lsp> {</div><div class='line'> static <data-lsp lsp='(property)</pre> MyClass.x: number' >x</data-lsp> = 0;</div><div class='line'> static <data-lsp lsp='(method)</pre> MyClass.printX(): void' > printX < /data-lsp > () { </div><div class='line'> <data-lsp lsp='var console: Console' >console</data-lsp>. <data-lsp lsp='(method) Console.log(...data: any[]): void' >log</data-lsp>(<data-lsp lsp='class MyClass' >MyClass</data-lsp>. <data-lsp lsp='(property) MyClass.x: number' >x</datalsp>);</div><div class='line'> }</div><div class='line'>}</div> <div class='line'><data-lsp lsp='var console: Console'</pre> >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span> (<data-lsp lsp='class</pre> MyClass' > MyClass < /data-lsp > . < data-lsp lsp='(property) MyClass.x: number' >x < /data-lsp >);</div><div class='line'> <data-lsp lsp='class MyClass' >MyClass</data-lsp>. <data-lsp lsp='(method) MyClass.printX(): void' >printX</data-lsp>();</div></code><a class='playground-link'

href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyCeBhcVoG8BQ1oQC5lwEthoAPaAXm
</div>

Static members can also use the same public, protected, and private visibility modifiers:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
MyClass' >MyClass</data-lsp></span><span style="color: #000000"> {</span></div><div
class='line'> < span style="color: #000000"> </span> < span style="color:
#0000FF">private</span><span style="color: #000000"> </span><span style="color:
#0000FF">static</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(property) MyClass.x: number' >x</data-lsp></span><span style="color:</pre>
#000000"> = </span><span style="color: #098658">0</span><span style="color: #000000">;
</span></div><div class='line'><span style="color: #000000">}</span></div><div
class='line'> < span style="color: #001080"> < data-lsp lsp='var console: Console' > console < /data-
lsp></span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='class MyClass'
>MyClass</data-lsp></span><span style="color: #000000">.</span><span style="color:
#001080"> <data-err> <data-lsp lsp='(property) MyClass.x: number' >x </data-lsp> </data-err>
</span><span style="color: #000000">);</span></div><span class="error"><span>Property 'x'
is private and only accessible within class 'MyClass'.</span><span class="code">2341</span>
</span><span class="error-behind">Property 'x' is private and only accessible within class
'MyClass'.</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBGAUAMYA2AhoogA
</div>
```

Static members are also inherited:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #00000FF"> class </span> <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='class Base' > Base</data-lsp> </span> <span style="color: #000000"> </span> <span style="color: #00000FF"> static </span> <span style="color: #000000"> </span> <span style="color: #00000FF"> static </span> <span style="color: #000000"> </span> <span style="color: #795E26"> <data-lsp lsp='(method)</td>Base.getGreeting(): string' >getGreeting </data-lsp> </span> <span style="color: #000000"> </span> </div> <div class='line'> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #00000FF"> class </span> <span style="color: #00000FFT"> class </span> <span style="color: #00000FFT"> class </span> <span style="color: #00000FFTT> class </span> <span style="color: #00000FTT> class </span> <span style="color: #00000FTT
```

#0000FF"> extends <data-lsp lsp='class Base' >Base </data-lsp> <data-lsp lsp='(property) Derived.myGreeting: string' >myGreeting</data-lsp> = <data-lsp lsp='class Derived' > Derived </data-lsp> . . . </div> <div class='line'> . </div> <div class='line'> . </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCkFNoG8BQ1oQC5iwS2GgHMEsBxAJ\ </div>

Special Static Names

It's generally not safe/possible to overwrite properties from the Function prototype. Because classes are themselves functions that can be invoked with new, certain static names can't be used. Function properties like name, length, and call aren't valid to define as static members:

<div class='code-container'> <code> <div class='line'> class <data-lsp lsp='class S' >S </data-lsp> { static = ; </div> Static property 'name' conflicts with built-in property 'Function.name' of constructor function 'S'. 2699 Static property 'name' conflicts with built-in property 'Function.name' of constructor function 'S'. <div class="line"> } </div> </code> <a class='playground-link'</pre>

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwDYCcWBQBjAGwENFFQBI </div>

Why No Static Classes?

TypeScript (and JavaScript) don't have a construct called static class the same way C# and Java do.

Those constructs *only* exist because those languages force all data and functions to be inside a class; because that restriction doesn't exist in TypeScript, there's no need for them. A class with only a single instance is typically just represented as a normal *object* in JavaScript/TypeScript.

For example, we don't need a "static class" syntax in TypeScript because a regular object (or even top-level function) will do the job just as well:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Unnecessary "static" class</div><div class='line'>class < span style="color: #267F99"> < data-lsp lsp='class MyStaticClass' >MyStaticClass</data-lsp> { </div><div class='line'> static <data-lsp lsp='(method) MyStaticClass.doSomething(): void' >doSomething</data-lsp> () {}</div><div class='line'><span style="color:</pre> #000000">}</div> <div class='line'>// Preferred (alternative 1) </div> <div class='line'> function <data-lsp lsp='function</pre> doSomething(): void' >doSomething</data-lsp>() {} </div> <div class='line'>// Preferred (alternative 2) </div><div class='line'>const <data-lsp lsp='const MyHelperObject: {
 dosomething(): void;
}' >MyHelperObject</data-lsp> = {</div><div class='line'> < span style="color: #000000">$ < span style="color: #795E26"> < data-lsp lsp='(method) dosomething(): void' >dosomething</data-lsp>() {},</div><div class='line'>};</div></code>Try</div>

Generic Classes

Classes, much like interfaces, can be generic. When a generic class is instantiated with new, its type parameters are inferred the same way as in a function call:

<div class='code-container'> <code> <div class='line'> class < <data-lsp lsp='class Box&lt;Type>' > Box </data-lsp > < <data-lsp lsp='(type parameter) Type in Box&lt;Type>' > Type </data-lsp> > { </div> <div class='line'> <data-lsp lsp='(property) Box&lt;Type> .contents: Type' > contents </data-lsp> : : ; </div> <div class='line'> ; </div> <div class='line'> ; </div> <div class='line'> ; </div> </div class='line'> </spa

```
#0000FF">constructor</span><span style="color: #000000">(</span><span style="color:
#001080"> < data-lsp lsp='(parameter) value: Type' > value < /data-lsp > </span> < span style="color:
#000000">: </span> <span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in
Box<Type>' >Type</data-lsp></span><span style="color: #000000">) {</span></div>
<div class='line'><span style="color: #000000"> </span><span style="color:</pre>
#0000FF">this</span><span style="color: #000000">.</span><span style="color: #001080">
<data-lsp lsp='(property) Box&amp;lt;Type>.contents: Type' >contents</data-lsp></span><span
style="color: #000000"> = </span><span style="color: #001080"> < data-lsp lsp='(parameter)
value: Type' >value</data-lsp></span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> }</span></div><div class='line'><span style="color:
#000000">}</span></div> <div class='line'><span style="color: #0000FF">const</span><span
style="color: #000000"> </span><span style="color: #0070C1"> < data-lsp lsp='const b:
Box<string>' >b</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #0000FF">new</span><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='constructor Box&amp;lt;string> (value: string): Box&amp;lt;string>'
>Box</data-lsp></span><span style="color: #000000">(</span><span style="color:
#A31515"> "hello!" </span> < span style="color: #000000">); </span> </div> < span class='popover-
prefix'> </span><span class='popover'><div class='arrow'></div>const b: Box&lt;string&gt;
</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCD2APAPAFQJ4AcCmA+aA3gFDTTDwl
</div>
```

Classes can use generic constraints and defaults the same way as interfaces.

Type Parameters in Static Members

This code isn't legal, and it may not be obvious why:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> class </span> <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='class Box&amp;lt;Type>' >Box</data-lsp lsp='(type parameter) Type in Box&amp;lt;Type>' >Type</data-lsp> </span> <span style="color: #267F99"> <data-lsp lsp='(type parameter) Type in Box&amp;lt;Type>' >Type</data-lsp> </span> <span style="color: #000000"> &gt; {</span> </div> <div class='line'> <span style="color: #000000"> </span> <span style="color: #0000FF"> static</span> <span style="color: #00000"> </span> <span style="color: #00000FF"> static</span> <span style="color: #00000"> </span> <span style="color: #001080"> <data-lsp lsp='(property)</td></rr>
Box&amp;lt;Type>.defaultValue: any' >defaultValue</data-lsp> </span> <span style="color: #267F99"> <data-err> <data-lsp lsp='any' >Type</data-lsp> </data-lsp> </data-err> </span> <span style="color: #000000">;</span> </div> <span class="error"> <span> Static members cannot reference class type parameters.</span> <span class="error"> <span> <span class="error"> <span> <span> <div class="line'> <span style="color: #000000"> </span> </div> </code> <a class='playground-link'</pre>
```

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAMaBQBjAGwENFFQAhAJb5QAE0gAzYgFdC-AGrFCsyKiasA3LgC+QA'>Try</div>

Remember that types are always fully erased! At runtime, there's only *one* Box.defaultValue property slot. This means that setting Box<string>.defaultValue (if that were possible) would *also* change Box<number>.defaultValue - not good. The static members of a generic class can never refer to the class's type parameters.

this at Runtime in Classes

<blockquote class='bg-reading'> Background Reading:
 this
keyword (MDN)
 </blockquote>

It's important to remember that TypeScript doesn't change the runtime behavior of JavaScript, and that JavaScript is somewhat famous for having some peculiar runtime behaviors.

JavaScript's handling of this is indeed unusual:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
MyClass' >MyClass</data-lsp></span><span style="color: #000000"> {</span></div><div

href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyCeBhcVoG8BQ1oDswFsBTaAXmgCIFII</div>

Long story short, by default, the value of this inside a function depends on *how the function was called*. In this example, because the function was called through the obj reference, its value of this was obj rather than the class instance.

This is rarely what you want to happen! TypeScript provides some ways to mitigate or prevent this kind of error.

Arrow Functions

If you have a function that will often be called in a way that loses its this context, it can make sense to use an arrow function property instead of a method definition:

```
lsp='(property) MyClass.name: string' >name</data-lsp> </span> <span style="color: #000000">
= </span><span style="color: #A31515">"MyClass"</span><span style="color: #000000">;
</span></div><div class='line'><span style="color: #000000"> </span><span style="color:
#795E26"> < data-lsp lsp='(property) MyClass.getName: () => string' > getName < /data-lsp>
<span> <span style="color: #000000"> = () <span> <span style="color: #0000FF">=>
</span><span style="color: #000000"> {</span></div><div class='line'><span style="color:
#000000"> </span><span style="color: #AF00DB">return</span><span style="color:
#000000"> </span><span style="color: #0000FF">this</span><span style="color: #000000">.
</span><span style="color: #001080"><data-lsp lsp='(property) MyClass.name: string'
>name</data-lsp></span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000"> };</span></div><div class='line'><span style="color:</pre>
#000000">}</span></div><div class='line'><span style="color: #0000FF">const</span><span
style="color: #000000"> </span><span style="color: #0070C1"> < data-lsp lsp='const c: MyClass'
>c</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#0000FF">new</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='constructor MyClass(): MyClass' > MyClass</data-lsp></span><span style="color:
#000000">();</span></div><div class='line'><span style="color: #0000FF">const</span><span
style="color: #000000"> </span><span style="color: #0070C1"> < data-lsp lsp='const q: () =>
string' >g</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#001080"> <data-lsp lsp='const c: MyClass' > c </data-lsp> </span> <span style="color:
#000000">.</span><span style="color: #001080"><data-lsp lsp='(property) MyClass.getName: ()
=> string' >getName</data-lsp></span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #008000">// Prints "MyClass" instead of crashing</span></div>
<div class='line'><span style="color: #001080"> <data-lsp lsp='var console: Console'</pre>
>console</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp > < /span>
<span style="color: #000000">(</span><span style="color: #795E26"> < data-lsp lsp='const g: ()</pre>
=> string' >g</data-lsp></span><span style="color: #000000">());</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECyCeBhcVoG8BQ1oDswFsBTaAXmgCIFII
</div>
```

This has some trade-offs:

- The this value is guaranteed to be correct at runtime, even for code not checked with TypeScript
- This will use more memory, because each class instance will have its own copy of each function defined this way
- You can't use super . getName in a derived class, because there's no entry in the prototype chain to fetch the base class method from

this parameters

In a method or function definition, an initial parameter named this has special meaning in TypeScript. These parameters are erased during compilation:

```
<div class='code-container'> <code> <div class='line'> <span style="color: #008000">// TypeScript input with &apos;this&apos; parameter </span> </div> <div class='line'> <span style="color: #00000FF">function </span> <span style="color: #000000"> </span> <span style="color: #795E26"> <data-lsp lsp='function fn(this: SomeType, x: number): void' >fn </data-lsp> </span> <span style="color: #000000"> </span> <span style="color: #00000FF"> <data-lsp lsp='function fn(this: SomeType, x: number): void' >fn </data-lsp> </span> <span style="color: #000000"> </span> <span style="color: #000000"> : </span> <span style="color: #000000"> : </span> <span style="color: #000000"> : </span> <span style="color: #001080"> <data-lsp lsp='type SomeType = any' >SomeType </data-lsp lsp='(parameter) x: number' >x</data-lsp </span> <span style="color: #001080"> </span> <data-lsp lsp='(parameter) x: number' >x</data-lsp> </span> <span style="color: #000000"> : </span> <data-lsp </td>
</rr>
</ra>

<pr
```

TypeScript checks that calling a function with a this parameter is done so with a correct context. Instead of using an arrow function, we can add a this parameter to method definitions to statically enforce that the method is called correctly:

<div class='code-container'> <code> <div class='line'> class <data-lsp lsp='class MyClass' >MyClass</data-lsp> { </div> <div class='line'> <data-lsp lsp='(property) MyClass.name: string' >name </data-lsp> = = ; </div> <div class='line'> <data-lsp lsp='(method) MyClass.getName(this: MyClass): string' >getName</data-lsp> : : </span style="color:

return this.<span</pre> style="color: #001080"> < data-lsp lsp='(property) MyClass.name: string' > name < /data-lsp> ;</div><div class='line'> }</div><div class='line'>}</div> <div class='line'>const <data-lsp lsp='const c: MyClass' >c</data-lsp> = new<span</pre> style="color: #000000"> < data-lsp lsp='constructor MyClass(): MyClass' > MyClass < /data-lsp > (); </div><div class='line'>// OK</div><div class='line'> < data-lsp lsp='const c: MyClass' > c < /data-lsp > <span</pre> style="color: #000000">.<data-lsp lsp='(method) MyClass.getName(this: MyClass): string' > getName < /data-lsp > < span style="color: #000000">();</div> <div class='line'>// Error, would crash</div><div class='line'>const < data-lsp lsp='const q: (this: MyClass) => string' >g</data-lsp> = < data-lsp lsp='const c: MyClass' > c < /data-lsp > < span style="color: #000000">.<data-lsp lsp='(method) MyClass.getName(this: MyClass): string' > getName < /data-lsp > < span style="color: #000000">;</div><div class='line'><data-lsp lsp='var console: Console' >console</data-lsp>. < data-lsp lsp='(method) Console.log(...data: any[]): void' > log < /data-lsp> (<data-lsp lsp='const g: (this: MyClass) => string' >q</data-lsp>()); </div> The 'this' context of type 'void' is not assignable to method's 'this' of type 'MyClass'.2684The 'this' context of type 'void' is not assignable to method's 'this' of type 'MyClass'.</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwDYAcAWAUAMYA2Ahoog/ </div>

This method takes the opposite trade-offs of the arrow function approach:

- JavaScript callers might still use the class method incorrectly without realizing it
- Only one function per class definition gets allocated, rather than one per class instance
- Base method definitions can still be called via super.

this Types

In classes, a special type called this refers *dynamically* to the type of the current class. Let's see how this is useful:

<!-- prettier-ignore --> class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> < div class='code-container'> < code> < div class='line'> < span #267F99"> <data-lsp lsp='class Box' > Box </data-lsp> < span style="color: #000000"> {</div><div class='line'> < data-lsp lsp='(property) Box.contents: string' > contents < /data-lsp > < span style="color: #000000">: string = "";</div><div class='line'> < data-lsp lsp='(method) Box.set(value: string): this' style='border-bottom: solid 2px lightgrey;'>set</data-lsp>(< data-lsp lsp='(parameter) value: string' > value < /data-lsp > : string<span</pre> style="color: #000000">) {</div> < div class='arrow'> </div> (method) Box.set(value: string): this < div class='line'> this .<data-lsp lsp='(property)</pre> Box.contents: string' >contents</data-lsp> = <data-lsp lsp='(parameter) value: string' >value</data-lsp> ;</div><div class='line'> return this; </div><div class='line'> }</div><div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/MYGwhqzhAEBCD2APaBvAUNax4DsAuApvhAFzQR4E </div>

Here, TypeScript inferred the return type of set to be this, rather than Box. Now let's make a subclass of Box:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span> < span style="color: #000000"> < / span> < span style="color: #267F99"> < data-lsp lsp='class </ span> < span style="color: #000000"> < / span> < span style="color: #000000"> < spa

```
>contents</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#A31515">""</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #000000"> }</span></div><div class='line'><span style="color: #000000">}
</span></div> <div class='line'><span style="color: #0000FF">const</span><span style="color:
#000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const a: ClearableBox'
>a</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#0000FF">new</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='constructor ClearableBox(): ClearableBox' > ClearableBox</data-lsp></span><span
style="color: #000000">();</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const b: ClearableBox' style='border-bottom: solid 2px lightgrey;'>b</data-lsp>
<span> <span style="color: #000000"> = </span> <span style="color: #001080"> <data-lsp
lsp='const a: ClearableBox' >a</data-lsp></span><span style="color: #000000">.</span><span
style="color: #795E26"> < data-lsp lsp='(method) Box.set(value: string): ClearableBox' > set < /data-
lsp></span><span style="color: #000000">(</span><span style="color: #A31515">"hello"
</span><span style="color: #000000">);</span></div><span class='popover-prefix'> </span>
<span class='popover'><div class='arrow'></div>const b: ClearableBox</span></code><a</pre>
class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCD2APaBvAUNax4DsAuApvhAFzQR4B
</div>
```

You can also use this in a parameter type annotation:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Box'</pre>
>Box</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)
Box.content: string' > content < /data-lsp > </span > <span style="color: #000000">: </span > <span
style="color: #267F99">string</span><span style="color: #000000"> = </span><span
style="color: #A31515">""</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) Box.sameAs(other: this): boolean' >sameAs</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) other: this'
>other</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">this</span><span style="color: #000000">) {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #AF00DB">return</span><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) other:
this' >other</data-lsp></span><span style="color: #000000">.</span><span style="color:
#001080"> < data-lsp lsp='(property) Box.content: string' > content < /data-lsp > </span> < span
style="color: #000000"> === </span><span style="color: #0000FF">this</span><span
style="color: #000000">.</span><span style="color: #001080"><data-lsp lsp='(property)
Box.content: string' > content < /data-lsp > </span > < span style="color: #000000">; </span > < /div >
```

<div class='line'> } </div> <div class='line'> } </div> </code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEBCD2APaBvAUNax4DsAuApvgFzQR4BC
</div>

This is different from writing other: Box -- if you have a derived class, its sameAs method will now only accept other instances of that same derived class:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class Box'</pre>
>Box</data-lsp></span><span style="color: #000000"> {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)
Box.content: string' > content < /data-lsp > </span > <span style="color: #000000">: </span > <span
style="color: #267F99">string</span><span style="color: #000000"> = </span><span
style="color: #A31515">""</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) Box.sameAs(other: this): boolean' >sameAs</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='(parameter) other: this'
>other</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">this</span><span style="color: #000000">) {</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #AF00DB">return</span><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(parameter) other:
this' >other</data-lsp></span><span style="color: #000000">.</span><span style="color:
#001080"> < data-lsp lsp='(property) Box.content: string' > content < /data-lsp > </span> < span
style="color: #000000"> === </span><span style="color: #0000FF">this</span><span
style="color: #000000">.</span><span style="color: #001080"><data-lsp lsp='(property)
Box.content: string' > content < /data-lsp > </span > < span style="color: #000000">; </span > < /div >
<div class='line'><span style="color: #000000"> }</span></div><div class='line'><span</pre>
style="color: #000000">}</span></div> <div class='line'><span style="color:

this -based type guards

You can use this is Type in the return position for methods in classes and interfaces. When mixed with a type narrowing (e.g. if statements) the type of the target object would be narrowed to the specified Type.

```

```

A common use-case for a this-based type guard is to allow for lazy validation of a particular field. For example, this case removes an undefined from the value held inside box when hasValue has been verified to be true:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class </ span> < span style="color: #000000"> </ span> < span style="color: #267F99"> < data-lsp lsp='class Box&lt;T>'> Box</data-lsp> </ span> < span style="color: #000000"> & lt; </ span> < span style="color: #000000"> < span style="color: #000000"> < span style="color: #000000"> < span> < span style="color: #000000"> < span sty

```
Box<T>.value?: T | undefined' >value</data-lsp></span><span style="color: #000000">?:
</span><span style="color: #267F99"><data-lsp lsp='(type parameter) T in Box&amp;lt;T>'
>T</data-lsp></span><span style="color: #000000">;</span></div> <div class='line'><span
style="color: #000000"> </span><span style="color: #795E26"> < data-lsp lsp='(method)
Box<T>.hasValue(): this is {&amp;#13; value: T;&amp;#13;}' >hasValue</data-lsp></span>
<span style="color: #000000">(): </span><span style="color: #0000FF">this</span><span</pre>

Parameter Properties

TypeScript offers special syntax for turning a constructor parameter into a class property with the same name and value. These are called *parameter properties* and are created by prefixing a constructor argument with one of the visibility modifiers <code>public</code>, <code>private</code>, <code>protected</code>, or <code>readonly</code>. The resulting field gets those modifier(s):

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class</span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
Params' > Params < /data-lsp > </span > < span style="color: #000000" > { </span > < /div > < div
class='line'><span style="color: #000000"> </span><span style="color:
#0000FF">constructor</span><span style="color: #000000">(</span></div><div class='line'>

Class Expressions

<blockquote class='bg-reading'> Background Reading:
 Class
expressions (MDN)
 </blockquote>

Class expressions are very similar to class declarations. The only real difference is that class expressions don't need a name, though we can refer to them via whatever identifier they ended up bound to:

someClass<Type>' >Type</data-lsp>; </div><div class='line'> constructor(< data-lsp lsp='(parameter) value: Type' > value < /data-lsp > < span style="color: #000000">: <data-lsp lsp='(type parameter) Type in someClass<Type>' >Type</data-lsp>) { </div><div class='line'> this. <data-lsp lsp='(property) someClass&lt;Type>.content: Type' >content</data-lsp> = < data-lsp</pre> lsp='(parameter) value: Type' >value</data-lsp>; </div><div class='line'> }</div><div class='line'>};</div> < div class='line'> < span style="color: #0000FF">const <data-lsp lsp='const m: someClass&lt;string>' >m</data-lsp> = new <data-lsp lsp='const someClass: new &lt;string> (value: string) => someClass<string>' >someClass</data-lsp>("Hello, world");</div> <div class='arrow'></div>const m: someClass<string></code><a class='playgroundlink'

href='https://www.typescriptlang.org/play/#code/MYewdgzgLgBBIFsCmBhANgQwhGBeGwm2APACoCe.</div>

abstract Classes and Members

Classes, methods, and fields in TypeScript may be abstract.

An abstract method or abstract field is one that hasn't had an implementation provided. These members must exist inside an abstract class, which cannot be directly instantiated.

The role of abstract classes is to serve as a base class for subclasses which do implement all the abstract members. When a class doesn't have any abstract members, it is said to be *concrete*.

Let's look at an example

```
 < div
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> abstract </ span>
  < span style="color: #000000"> </ span> < span style="color: #0000FF"> class </ span> < span
  style="color: #000000"> </ span> < span style="color: #267F99"> < data-lsp lsp='class Base'
  >Base < /data-lsp> < /span> < span style="color: #000000"> {</span> < /div> < div class='line'>
  < span style="color: #000000"> </span> < span style="color: #0000FF"> abstract </span> < span</pre>
```

```
style="color: #000000"> </span><span style="color: #795E26"> < data-lsp lsp='(method)
Base.getName(): string' > getName < /data-lsp > </span > <span style="color: #000000">(): </span >
<span style="color: #267F99">string</span><span style="color: #000000">;</span></div> <div</pre>
class='line'><span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp
lsp='(method) Base.printName(): void' > printName</data-lsp> </span> < span style="color:
#000000">() {</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='var console: Console' > console < /data-lsp > </span> < span
style="color: #000000">.</span><span style="color: #795E26"><data-lsp lsp='(method)
Console.log(...data: any[]): void' >log</data-lsp> </span> <span style="color: #000000">(</span>
<span style="color: #A31515">"Hello, "</span><span style="color: #000000"> + </span><span</pre>
style="color: #0000FF">this</span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='(method) Base.getName(): string' > getName < /data-lsp > </span> < span
style="color: #000000">());</span></div><div class='line'><span style="color: #000000"> }
</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #0000FF">const</span><span style="color: #000000"> </span>
<span style="color: #0070C1"> <data-lsp lsp='const b: any' > b < /data-lsp> </span> <span</pre>
style="color: #000000"> = </span><span style="color: #0000FF">new</span><span
style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='constructor Base():
Base' >Base</data-lsp></span><span style="color: #000000">();</span></div><span
class="error"> < span> Cannot create an instance of an abstract class. < / span> < span
class="code">2511</span></span><span class="error-behind">Cannot create an instance of an
abstract class.</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYCMWBQBDAI0QBdp8Bj
</div>
```

We can't instantiate Base with new because it's abstract. Instead, we need to make a derived class and implement the abstract members:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #0000FF"> class </span> <span style="color: #00000F"> </span> <span style="color: #267F99"> <data-lsp lsp='class Derived'> Derived </data-lsp> </span> <span style="color: #000000"> </span> </span> </div> <div class='line'> <span style="color: #000000"> </span> </div> <div class='line'> <span style="color: #000000"> </span> </div> <div class='line'> <span style="color: #000000"> </span> </span> </div> <div class='line'> <span style="color: #000000"> </span> </s
```

style="color: #000000"> = new new <data-lsp lsp='constructor
Derived(): Derived' > Derived </data-lsp> (); </div> <div class='line'> <data-lsp lsp='const d: Derived' > d</data-lsp> . <data-lsp lsp='(method) Base.printName(): void' > printName </data-lsp> (); </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/IYIwzgLgTsDGEAJYBthjAgQmgpgg3gFAIKiQzwIDmOE/ek1ZsCAX0IKA9EoQBaDbACuEDWslo0GACI4JANxwATBDgAeEHHysZsYPERI0pzdgREkULRaUHwIAEQA7@ </div>

Notice that if we forget to implement the base class's abstract members, we'll get an error:

<div class='code-container'> <code> <div class='line'> class <data-err> <data-lsp lsp='class Derived'> Derived </data-lsp> </data-err> extends <data-lsp lsp='class Base'> Base </data-lsp> { </div> Non-abstract class 'Derived' does not implement inherited abstract member 'getName' from class 'Base'. 2515 Non-abstract class 'Derived' does not implement inherited abstract member 'getName' from class 'Base'. <div class='line'> // forgot to do anything </div> <div class='line'> { { </div> </code> <a class='playground-link'</pre>

href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYCMGBQBDAI0QBdp8BjF </div>

Abstract Construct Signatures

Sometimes you want to accept some class constructor function that produces an instance of a class which derives from some abstract class.

For example, you might want to write this code:

< div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < span style="color: #000000"> < span style="color: #795E26"> < data-lsp lsp='function greet(ctor: typeof Base): void' > greet < /data-lsp> < /span> < span style="color: #000000"> < (data-lsp) lsp='(parameter) ctor: typeof Base' > ctor < /data-lsp> < /span> < span style="color: #000000">: < span style="color: #00000FF"> typeof < span style="color: #000000"> < /span> < span style="color: #001080"> < data-lsp lsp='class Base' > Base < /data-lsp> < /span> < span style="color: #000000"> (< /div> < div class='line'> < /div>

```
<span style="color: #000000"> </span><span style="color: #0000FF">const</span><span</pre>
style="color: #000000"> </span><span style="color: #0070C1"> < data-lsp lsp='const instance:
any' >instance</data-lsp></span><span style="color: #000000"> = </span><span style="color:
#0000FF">new</span><span style="color: #000000"> </span><span style="color: #795E26">
<data-lsp lsp='(parameter) ctor: abstract new () => Base' >ctor</data-lsp></span><span
style="color: #000000">();</span></div><span class="error"><span>Cannot create an instance
of an abstract class.</span><span class="code">2511</span></span><span class="error-
behind">Cannot create an instance of an abstract class.</span><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='const instance:
any' >instance</data-lsp></span><span style="color: #000000">.</span><span style="color:
#795E26"> < data-lsp lsp='any' > printName < /data-lsp> < /span> < span style="color: #000000">();
</span></div><div class='line'><span style="color: #000000">}</span></div></code><a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwFYCMWBQBDAI0QBdp8Bj
</div>
```

TypeScript is correctly telling you that you're trying to instantiate an abstract class. After all, given the definition of greet, it's perfectly legal to write this code, which would end up constructing an abstract class:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000"> // Bad! < /span>
</div><div class='line'><span style="color: #795E26"><data-lsp lsp='const greet: any'
>greet</data-lsp></span><span style="color: #000000">(</span><span style="color:
#001080"> <data-lsp lsp='const Base: any' > Base </data-lsp> </span> < span style="color:
#000000">);</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/CYUwxgNghgTiAEYD2A7AzgF3gcziDAXPFCgJ4A08AQ
ALQ9gCuGHl3acawAlQtclfAAoadAJRMgA'>Try</a></div>
```

Instead, you want to write a function that accepts something with a construct signature:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
greet(ctor: new () => Base): void' > greet < /data-lsp> < /span> < span style="color: #000000">
(</span> < span style="color: #001080"> < data-lsp lsp='(parameter) ctor: new () => Base'
>ctor</data-lsp></span><span style="color: #000000">: </span><span style="color:
#AF00DB">new</span><span style="color: #000000"> () </span><span style="color:
#0000FF">=></span><span style="color: #000000"> </span><span style="color: #267F99">
<data-lsp lsp='class Base' >Base</data-lsp></span><span style="color: #000000">) {</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const instance: Base' >instance</data-lsp></span><span style="color: #000000">
= </span><span style="color: #0000FF">new</span><span style="color: #000000"> </span>
```

 < data-lsp lsp='(parameter) ctor: new () => Base' > ctor < /data-lsp> ();</div><div class='line'> <data-lsp lsp='const instance: Base' >instance</data-lsp>. < data-lsp lsp='(method) Base.printName(): void' > printName < /data-lsp > < /span> (); </div> < div class='line'> < span style="color:</pre> #000000">}</div><div class='line'><data-lsp lsp='function greet(ctor: new () => Base): void' > greet < /data-lsp> < span style="color:</pre> #000000">(<data-lsp lsp='class Derived' > Derived</datalsp>);</div><div class='line'> < data-lsp lsp='function greet(ctor: new () => Base): void' > greet < / data-lsp > < / span> (<data-err> <data-lsp</pre> lsp='class Base' > Base < /data-lsp> < /data-err> < /span> < span style="color: #000000">); < /span> </div>Argument of type 'typeof Base' is not assignable to parameter of type 'new () = &qt; Base'. Cannot assign an abstract constructor type to a non-abstract constructor type.2345Argument of type 'typeof Base' is not assignable to parameter of type 'new () => Base'. Cannot assign an abstract constructor type to a non-abstract constructor type.</code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFMCdoe2gZwFygEwGYAsBWAUAIYBGiALtAQN

ref="https://www.typescriptlang.org/play/#code/PIAEAEFMCdoe2g2wFygEwGYAsBWAUAIYBGIALtAQI"
</div>

Now TypeScript correctly tells you about which class constructor functions can be invoked - Derived can because it's concrete, but Base cannot.

Relationships Between Classes

In most cases, classes in TypeScript are compared structurally, the same as other types.

For example, these two classes can be used in place of each other because they're identical:

<div class='code-container'> <code> <div class='line'> class class <data-lsp lsp='class </div> <div class='line'> Point1 </data-lsp> { </div> <div class='line'> <data-lsp lsp='(property) Point1.x: number' >x</data-lsp> = ; </div> <div class='line'> <data-lsp lsp='(property) Point1.y: number' >y </data-lsp> = ; </div> <div class='line'> ; </div> <div class='line'> ; </div> <div class='line'>

```
#267F99"> < data-lsp lsp='class Point2' > Point2 < /data-lsp > </span> < span style="color:
#000000"> {</span> </div> <div class='line'> <span style="color: #000000"> </span> <span
style="color: #001080"> < data-lsp lsp='(property) Point2.x: number' > x < /data-lsp > < /span> < span
style="color: #000000"> = </span><span style="color: #098658">0</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(property) Point2.y: number' > y < /data-lsp > </span> < span
style="color: #000000"> = </span><span style="color: #098658">0</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #008000">// OK</span></div><div class='line'><span
style="color: #0000FF">const</span><span style="color: #000000"> </span><span style="color:
#0070C1"> < data-lsp lsp='const p: Point1' >p < /data-lsp> < /span> < span style="color: #000000">:
</span><span style="color: #267F99"><data-lsp lsp='class Point1' > Point1 < /data-lsp> < /span>
<span style="color: #000000"> = </span><span style="color: #0000FF">new</span><span</pre>
style="color: #000000"> </span><span style="color: #795E26"> < data-lsp lsp='constructor
Point2(): Point2' > Point2 < /data-lsp > </span > < span style="color: #000000" > (); </span > < /div >
</code> <a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAEAKD2BLAdgFwlzQN4ChrQA9oBeaABgG
</div>
```

Similarly, subtype relationships between classes exist even if there's no explicit inheritance:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
Person' >Person</data-lsp></span><span style="color: #000000"> {</span></div><div
class='line'> < span style="color: #000000"> </span> < span style="color: #001080"> < data-lsp
lsp='(property) Person.name: string' >name</data-lsp></span><span style="color: #000000">:
</span><span style="color: #267F99">string</span><span style="color: #000000">;</span>
</div><div class='line'><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(property) Person.age: number' >age</data-lsp></span><span style="color:</pre>
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F999999
#000000">;</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #0000FF">class</span><span style="color: #000000"> </span>
<span style="color: #267F99"> <data-lsp lsp='class Employee' > Employee < /data-lsp > </span>
<span style="color: #000000"> {</span></div><div class='line'><span style="color: #000000">
</span> < span style="color: #001080"> < data-lsp lsp='(property) Employee.name: string'
>name</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">string</span><span style="color: #000000">;</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)
Employee.age: number' >age</data-lsp></span><span style="color: #000000">: </span><span
style="color: #267F99">number</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) Employee.salary: number' >salary</data-lsp></span><span style="color:
#000000">: </span> <span style="color: #267F99"> number </span style="color: #267F999"> number </span style="color: #267F9999"> number </span style="color: #267F9999"> number </span style="color: #267F9999</span style="c
```

This sounds straightforward, but there are a few cases that seem stranger than others.

Empty classes have no members. In a structural type system, a type with no members is generally a supertype of anything else. So if you write an empty class (don't!), anything can be used in place of it:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> class < / span>
<span style="color: #000000"> </span><span style="color: #267F99"> <data-lsp lsp='class</pre>
Empty' > Empty < /data-lsp > </span > < span style="color: #000000" > {} </span > < /div > < div
class='line'><span style="color: #0000FF">function</span><span style="color: #000000">
</span><span style="color: #795E26"><data-lsp lsp='function fn(x: Empty): void' >fn</data-lsp>
</span><span style="color: #000000">(</span><span style="color: #001080"><data-lsp
lsp='(parameter) x: Empty' >x</data-lsp></span><span style="color: #000000">: </span><span
style="color: #267F99"> < data-lsp lsp='class Empty' > Empty < /data-lsp > </span> < span
style="color: #000000">) {</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #008000">// can&apos;t do anything with &apos;x&apos;, so I
won't</span></div><div class='line'><span style="color: #000000">}</span></div> <div
class='line'><span style="color: #008000">// All OK!</span></div><div class='line'><span
style="color: #795E26"> < data-lsp lsp='function fn(x: Empty): void' > fn < /data-lsp > </span> < span
style="color: #000000">(</span><span style="color: #001080"><data-lsp lsp='var window:
Window & Dindow & Span Style="color: window & January Span Style="color: window & Span
#000000">);</span></div><div class='line'><span style="color: #795E26"><data-lsp
lsp='function fn(x: Empty): void' >fn</data-lsp></span><span style="color: #000000">({});
</span> </div> <div class='line'> <span style="color: #795E26"> <data-lsp lsp='function fn(x:
Empty): void' >fn</data-lsp></span><span style="color: #000000">(</span><span style="color: #000000")
#001080"> <data-lsp lsp='function fn(x: Empty): void' > fn < /data-lsp > </span> < span style="color:
#000000">);</span></div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/MYGwhgzhAECiC2AHALgT2gbwL4CgcDMBXAO2GQE
</div>
```

Modules

JavaScript has a long history of different ways to handle modularizing code. TypeScript having been around since 2012, has implemented support for a lot of these formats, but over time the community and the JavaScript specification has converged on a format called ES Modules (or ES6 modules). You might know it as the import / export syntax.

ES Modules was added to the JavaScript spec in 2015, and by 2020 had broad support in most web browsers and JavaScript runtimes.

For focus, the handbook will cover both ES Modules and its popular pre-cursor CommonJS module.exports = syntax, and you can find information about the other module patterns in the reference section under Modules.

How JavaScript Modules are Defined

In TypeScript, just as in ECMAScript 2015, any file containing a top-level import or export is considered a module.

Conversely, a file without any top-level import or export declarations is treated as a script whose contents are available in the global scope (and therefore to modules as well).

Modules are executed within their own scope, not in the global scope. This means that variables, functions, classes, etc. declared in a module are not visible outside the module unless they are explicitly exported using one of the export forms. Conversely, to consume a variable, function, class, interface, etc. exported from a different module, it has to be imported using one of the import forms.

Non-modules

Before we start, it's important to understand what TypeScript considers a module. The JavaScript specification declares that any JavaScript files without an export or top-level await should be considered a script and not a module.

Inside a script file variables and types are declared to be in the shared global scope, and it's assumed that you'll either use the <u>--outFile</u> compiler option to join multiple input files into one output file, or use multiple <script> tags in your HTML to load these files (in the correct order!).

If you have a file that doesn't currently have any import s or export s, but you want to be treated as a module, add the line:

< div class='code-container'> < code> < div class='line'> < span style="color: #AF00DB"> export < / span> < span style="color: #000000"> {}; < / span> < / div> < / code> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/KYDwDg9gTgLgBAbwL4G4g'>Try < / a> < / div>

which will change the file be a module exporting nothing. This syntax works regardless of your module target.

Modules in TypeScript

<blockquote class='bg-reading'> Additional Reading:
 Impatient JS (Modules)
 MDN: JavaScript Modules

</blockquote>

There are three main things to consider when writing module-based code in TypeScript:

- **Syntax**: What syntax do I want to use to import and export things?
- Module Resolution: What is the relationship between module names (or paths) and files on disk?
- Module Output Target: What should my emitted JavaScript module look like?

ES Module Syntax

A file can declare a main export via export default:

href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKAFvWsB7AOgBcBnAKF </div>

This is then imported via:

In addition to the default export, you can have more than one export of variables and functions via the export by omitting default:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000"> // @filename:
maths.ts</span></div><div class='line'><span style="color: #AF00DB">export</span><span
style="color: #000000"> </span><span style="color: #0000FF">var</span><span style="color:
#000000"> </span><span style="color: #001080"> <data-lsp lsp='var pi: number' >pi </data-lsp>
<span> <span style="color: #000000"> = </span> <span style="color: #098658">3.14</span>
<span style="color: #000000">;</span></div><div class='line'><span style="color:</pre>
#AF00DB">export</span><span style="color: #000000"> </span><span style="color:
#0000FF">let</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='let squareTwo: number' >squareTwo</data-lsp></span><span style="color:</pre>
#000000"> = </span><span style="color: #098658">1.41</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #AF00DB">export</span><span
style="color: #000000"> </span><span style="color: #0000FF">const</span><span style="color:
#000000"> </span><span style="color: #0070C1"> <data-lsp lsp='const phi: 1.61' > phi </data-
lsp></span><span style="color: #000000"> = </span><span style="color:
#098658">1.61</span><span style="color: #000000">;</span></div> <div class='line'><span
style="color: #AF00DB">export</span><span style="color: #000000"> </span><span
style="color: #0000FF">class</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='class RandomNumberGenerator' > RandomNumberGenerator < /data-
lsp></span><span style="color: #000000"> {}</span></div> <div class='line'><span
style="color: #AF00DB">export</span><span style="color: #000000"> </span><span
style="color: #0000FF">function</span><span style="color: #000000"> </span><span
style="color: #795E26"> < data-lsp lsp='function absolute(num: number): number'
>absolute</data-lsp></span><span style="color: #000000">(</span><span style="color:
```

#001080"> < data-lsp lsp='(parameter) num: number' > num < /data-lsp > < span style="color: #000000">: number) {</div><div class='line'> if (< data-lsp lsp='(parameter) num: number' > num < /data-lsp > < 0<span</pre> style="color: #000000">) return < data-lsp lsp='(parameter) num: #098658">1;</div><div class='line'> return <data-lsp lsp='(parameter) num: number' > num < /data-lsp> < /span> < span style="color: #000000">; < /span> < /div> < div class='line'>}</div></code><a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKVyAuALAZwDpdCAoe/ </div>

These can be used in another file via the import syntax:

 < div</pre> class='code-container'> < code> < div class='line'> < span style="color: #AF00DB"> import < / span> { < data-lsp lsp='(alias) var</pre> pi: number
import pi' >pi</data-lsp> < span style="color: #000000">, <data-lsp lsp='(alias) const phi: 1.61&#13;import phi'</pre> >phi</data-lsp>, <data-lsp lsp='(alias) function absolute(num: number): number&#13;import absolute'</p> >absolute</data-lsp> } from "./maths.js";</div> <div class='line'> < data-lsp lsp='var console: Console' > console < /data-lsp > . < data-lsp lsp='(method)</pre> Console.log(...data: any[]): void' >log</data-lsp>(<data-lsp lsp='(alias) var pi: number&#13;import pi' >pi</data-lsp>);</div><div class='line'>const < data-lsp lsp='const absPhi: number' style='border-bottom: solid 2px lightgrey;'>absPhi</data-lsp> = < data-lsp lsp='(alias) absolute(num: number): number&#13;import absolute' >absolute</data-lsp> (< data-lsp lsp='(alias) const phi: 1.61&#13;import phi' > phi < /datalsp>);</div> <div class='arrow'></div>const absPhi: number </code> <a class='playground-link'

href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKVyAuALAZwDpdCAoe/

</div>

Additional Import Syntax

An import can be renamed using a format like import {old as new}:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #AF00DB"> import < / span>
<span style="color: #000000"> { </span><span style="color: #001080"> < data-lsp lsp='var pi:</pre>
number' >pi</data-lsp></span><span style="color: #000000"> </span><span style="color:
#AF00DB">as</span><span style="color: #000000"> </span><span style="color: #001080">
<data-lsp lsp='(alias) var π: number&amp;#13;import Ï€' >Ï€</data-lsp></span><span
style="color: #000000"> } </span><span style="color: #AF00DB">from</span><span
style="color: #000000"> </span><span style="color: #A31515">"./maths.js"</span><span
style="color: #000000">;</span></div> <div class='line'><span style="color: #001080"><data-
lsp lsp='var console: Console' > console</data-lsp></span><span style="color: #000000">.
</span><span style="color: #795E26"><data-lsp lsp='(method) Console.log(...data: any[]): void'
>log</data-lsp></span><span style="color: #000000">(</span><span style="color: #001080">
<data-lsp lsp='(alias) var π: number&amp;#13;import Ï€' >Ï€</data-lsp></span><span
style="color: #000000">);</span></div><span class='popover-prefix'> </span><span
class='popover'> <div class='arrow'> </div>(alias) var π: number import Ï€ </span> </code> <a
class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKVyAuALAZwDpdCAoe/
EA'>Try</a></div>
```

You can mix and match the above syntax into a single import:

```
 <div class='code-container'> <code> <div class='line'> <span style="color: #008000"> // @filename: maths.ts </span> </div> <div class='line'> <span style="color: #AF00DB"> export </span> <span style="color: #000000"> </span> <span style="color: #0000FF"> const </span> <span style="color: #000000"> </span> <span style="color: #0070C1"> <data-lsp lsp='const pi: 3.14' >pi </data-lsp> </span> <span style="color: #000000"> = </span> <span style="color: #098658"> 3.14 </span> <span style="color: #000000"> </span> <span style="color: #098658"> 3.14 </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #000000"> </span> <span style="color: #00000"> </span> <span style="color: #00000"> </span> <span style="color: #267F99"> <data-lsp lsp='class </span> <span style="color: #000000"> </span> <span style="color: #267F99"> <data-lsp lsp='class RandomNumberGenerator' >RandomNumberGenerator </data-lsp > </span> <span style="color: #000000"> </span> <span style="color: #00000"> </span> <span style="color: #0000
```

```
<span> <span style="color: #000000">, { <span> <span style="color: #001080"> <data-lsp
lsp='const pi: 3.14' >pi</data-lsp></span><span style="color: #000000"> </span><span
style="color: #AF00DB">as</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(alias) const π: 3.14&amp;#13;import Ï€' >Ï€ < /data-lsp> < /span> < span
style="color: #000000"> } </span><span style="color: #AF00DB">from</span><span
style="color: #000000"> </span><span style="color: #A31515">"./maths.js"</span><span
style="color: #000000">;</span></div> <div class='line'><span style="color: #001080"><data-
lsp lsp='(alias) class RNGen
import RNGen' >RNGen</data-lsp></span><span
style="color: #000000">;</span></div><span class='popover-prefix'> </span><span
class='popover'> < div class='arrow'> </div> (alias) class RNGen import RNGen </span> < div
class='line'><span style="color: #001080"><data-lsp lsp='var console: Console' >console</data-
lsp></span><span style="color: #000000">.</span><span style="color: #795E26"><data-lsp
lsp='(method) Console.log(...data: any[]): void' >log</data-lsp></span><span style="color:
#000000">(</span><span style="color: #001080"><data-lsp lsp='(alias) const π:
3.14
import π' >Ï€</data-lsp></span><span style="color: #000000">);</span></div>
<span class='popover-prefix'> </span><span class='popover'> < div class='arrow'> </div>(alias)
const π: 3.14 import Ï€</span></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKVyAuALAZwDpdCAoe/
</div>
```

You can take all of the exported objects and put them into a single namespace using * as name:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #008000">// @filename:
app.ts</span></div><div class='line'><span style="color: #AF00DB">import</span><span
style="color: #000000"> </span><span style="color: #0000FF">*</span><span style="color:
#000000"> </span><span style="color: #AF00DB">as</span><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='import math' > math </data-lsp> </span>
<span style="color: #000000"> </span><span style="color: #AF00DB">from</span><span</pre>
style="color: #000000"> </span><span style="color: #A31515">"./maths.js"</span><span
style="color: #000000">;</span></div> <div class='line'> <span style="color: #001080"> <data-
lsp lsp='var console: Console' > console</data-lsp></span><span style="color: #000000">.
</span><span style="color: #795E26"><data-lsp lsp='(method) Console.log(...data: any[]): void'
>log</data-lsp></span><span style="color: #000000">(</span><span style="color: #001080">
<data-lsp lsp='import math' >math</data-lsp></span><span style="color: #000000">.</span>
<span style="color: #001080"> <data-lsp lsp='var pi: number' > pi </data-lsp > </span> < span</pre>
style="color: #000000">);</span></div><div class='line'><span style="color:
#0000FF">const</span><span style="color: #000000"> </span><span style="color: #0070C1">
<data-lsp lsp='const positivePhi: number' style='border-bottom: solid 2px
lightgrey;'>positivePhi</data-lsp></span><span style="color: #000000"> = </span><span
style="color: #001080"> < data-lsp lsp='import math' > math < /data-lsp> < /span> < span
style="color: #000000">.</span><span style="color: #795E26"><data-lsp lsp='function
absolute(num: number): number' > absolute < /data-lsp > </span > < span style = "color: #000000" >
```

```
(</span> <span style="color: #001080"> <data-lsp lsp='import math' >math </data-lsp> </span> <span style="color: #000000">.</span> <span style="color: #001080"> <data-lsp lsp='const phi: 1.61' >phi </data-lsp> </span> <span style="color: #000000">); </span> </div> <span class='popover-prefix'> </span> <span class='popover'> <div class='arrow'> </div> const positivePhi: number </span> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKVyAuALAZwDpdCAoe/GhpSCmhUN0b-Qmw8fFBIBjpUUAAiYmAcAhlAK0JjiXJzSxD4Ylg6AHMli-xiLmSJR5WTh0QjQHwseAABVs2m+xECwVC4S+O1+tn+kyyWQAegB+IA'>Try </a> </div>
```

You can import a file and *not* include any variables into your current module via import "./file":

```
 class="shiki light-plus twoslash lsp" style="background-color: #FFFFFF; color: #000000"> <div class='code-container'> <code> <div class='line'> <span style="color: #008000"> // @filename: app.ts </span> </div> <div class='line'> <span style="color: #AF00DB"> import </span> <span style="color: #000000"> </span> <span style="color: #A31515"> "./maths.js" </span> <span style="color: #000000"> ;</span> <span style="color: #001080"> <data-lsp lsp='var console: Console' >console</data-lsp> </span> <span style="color: #000000"> .</span> </span> </span> </span> <span style="color: #000000"> .</span> </span> </span
```

In this case, the import does nothing. However, all of the code in maths.ts was evaluated, which could trigger side-effects which affect other objects.

TypeScript Specific ES Module Syntax

Types can be exported and imported using the same syntax as JavaScript values:

```
#AF00DB">export</span><span style="color: #000000"> </span><span style="color:
#0000FF">interface</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='interface Dog' > Dog < /data-lsp > </span> < span style="color:
#000000"> {</span> </div> <div class='line'> <span style="color: #000000"> </span> <span
style="color: #001080"> < data-lsp lsp='(property) Dog.breeds: string[]' > breeds < /data-lsp>
</span><span style="color: #000000">: </span><span style="color: #267F99">string</span>
<span style="color: #000000">[];</span></div><div class='line'><span style="color: #000000">
</span><span style="color: #001080"><data-lsp lsp='(property) Dog.yearOfBirth: number'
>yearOfBirth</data-lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000">;</span></div><div class='line'>
<span style="color: #000000">}</span></div> <div class='line'><span style="color:</pre>
#008000">// @filename: app.ts</span></div><div class='line'><span style="color:
#001080"> < data-lsp lsp='(alias) type Cat = {&amp;#13; breed: string;&amp;#13; yearOfBirth:
number;
}
import Cat' > Cat < /data-lsp > </span > < span style="color:
#000000">, </span><span style="color: #001080"> < data-lsp lsp='(alias) interface
Dog
import Dog' > Dog</data-lsp></span><span style="color: #000000"> } </span>
<span style="color: #AF00DB">from</span><span style="color: #000000"> </span><span</pre>
style="color: #A31515">"./animal.js"</span><span style="color: #000000">;</span></div><div
class='line'><span style="color: #0000FF">type</span><span style="color: #000000"> </span>
<span style="color: #267F99"> < data-lsp lsp='type Animals = Cat | Dog' > Animals < /data-lsp>
</span><span style="color: #000000"> = </span><span style="color: #267F99"> <data-lsp
lsp='(alias) type Cat = {
 breed: string;
 yearOfBirth:
number;
}
import Cat' > Cat < /data-lsp > </span > < span style="color:
#000000"> | </span> <span style="color: #267F99"> <data-lsp lsp='(alias) interface
Dog
import Dog' > Dog < /data-lsp > </span > <span style="color: #000000">; </span >
</div></code><a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKZjqubAHQAuAzgFDwA
spAA'>Try</a></div>
```

TypeScript has extended the import syntax with import type which is an import which can *only* import types.

< div class='code-container'> < code> < div class='line'> < span style="color: #008000"> // @filename: animal.ts < /div> < div class='line'> < span style="color: #AF00DB"> export < span style="color: #00000"> < span style="color: #0000FF"> type < span style="color: #00000"> < span style="color: #267F99"> < data-lsp lsp='type Cat = {&#13; breed: string;&#13; yearOfBirth: number;&#13;}' > Cat < /data-lsp | sp='(property) breed: string' > breed < /data-lsp> < / span> < span style="color: #001080"> < data-lsp lsp='(property) breed: string' > breed < /data-lsp | sp='(span> < span style="color: #000000"> : < span style="color: #001080"> < data-lsp | sp='(property) yearOfBirth: number' > yearOfBirth < /data-lsp | sp='(span> < span) < < span style="color: #001080"> < data-lsp | sp='(property) yearOfBirth: number' > yearOfBirth < /data-lsp > < span > < span >

```
style="color: #000000">: </span><span style="color: #267F99">number</span><span
style="color: #000000"> };</span></div><span class="error"><span>'createCatName' cannot be
used as a value because it was imported using 'import type'.</span><span
class="code">1361</span></span><span class="error-behind">'createCatName' cannot be used
as a value because it was imported using 'import type'.</span><div class='line'><span
style="color: #AF00DB">export</span><span style="color: #000000"> </span><span
style="color: #0000FF">type</span><span style="color: #000000"> </span><span style="color:
#267F99"> < data-lsp lsp='type Dog = {&amp;#13; breeds: string[];&amp;#13; yearOfBirth:

#000000">;</span></div> <div class='line'><span style="color: #008000">// @filename:
app.ts</span></div><div class='line'><span style="color: #AF00DB">import</span><span
style="color: #000000"> </span><span style="color: #AF00DB">type</span><span style="color:
#000000"> { </span> < span style="color: #001080"> < data-lsp lsp='(alias) const createCatName:
() => string
import createCatName' >createCatName</data-lsp></span><span
```

```
style="color: #000000"> } </span><span style="color: #AF00DB">from </span><span style="color: #A90000"> ;</span><span style="color: #A31515"> "./animal.js" </span> <span style="color: #000000"> ;</span> </div> <div class='line'> <span style="color: #0070C1"> <data-lsp lsp='color: #0070C1"> <data-lsp lsp='const name: string' >name </data-lsp </span> <span style="color: #000000"> = </span> <span style="color: #795E26"> <data-lsp lsp='(alias) createCatName(): string&amp;#13;import createCatName' >createCatName </data-lsp> </span> <span style="color: #00000"> ();</span> </div> </code> <a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEDMEsBsFMB2BDAtvAXKZjqubAHQAuAzgFDwA </div>
```

This syntax allows a non-TypeScript transpiler like Babel, swc or esbuild to know what imports can be safely removed.

ES Module Syntax with CommonJS Behavior

TypeScript has ES Module syntax which *directly* correlates to a CommonJS and AMD require. Imports using ES Module are *for most cases* the same as the require from those environments, but this syntax ensures you have a 1 to 1 match in your TypeScript file with the CommonJS output:

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #AF00DB"> import < / span>
<span style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(alias)</pre>
module & amp; quot; fs & amp; quot; & amp; #13; import fs = require(& amp; quot; fs & amp; quot;)'

<a class='playground-link'
href='https://www.typescriptlang.org/play/#code/PQqEB4CcFMDNpgOwMbVAFwJ4AdoGcBeAlkQHsATa
```

You can learn more about this syntax in the modules reference page.

</div>

CommonJS Syntax

CommonJS is the format which most modules on npm are delivered in. Even if you are writing using the ES Modules syntax above, having a brief understanding of how CommonJS syntax works will help you debug easier.

Exporting

Identifiers are exported via setting the exports property on a global called module.

```
 < div</pre>
class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> function < / span>
<span style="color: #000000"> </span><span style="color: #795E26"> <data-lsp lsp='function</pre>
absolute(num: number): number' > absolute < /data-lsp > </span > < span style = "color: #000000" >
(</span> <span style="color: #001080"> <data-lsp lsp='(parameter) num: number' > num </data-
lsp></span><span style="color: #000000">: </span><span style="color:
#267F99">number</span><span style="color: #000000">) {</span></div><div class='line'>
<span style="color: #000000"> </span><span style="color: #AF00DB">if</span><span</pre>
style="color: #000000"> (</span><span style="color: #001080"> <data-lsp lsp='(parameter) num:
number' > num < /data-lsp > </span > <span style="color: #000000" > &lt; </span > <span
style="color: #098658">0</span><span style="color: #000000">) </span><span style="color:
#AF00DB">return</span><span style="color: #000000"> </span><span style="color:
#001080"> < data-lsp lsp='(parameter) num: number' > num < /data-lsp > </span> < span
style="color: #000000"> * -</span><span style="color: #098658">1</span><span style="color:
#000000">;</span></div><div class='line'><span style="color: #000000"> </span><span
style="color: #AF00DB">return</span><span style="color: #000000"> </span><span
style="color: #001080"> < data-lsp lsp='(parameter) num: number' > num < /data-lsp > </span>
<span style="color: #000000">;</span></div><div class='line'><span style="color: #000000">}
</span></div> <div class='line'><span style="color: #267F99"><data-lsp lsp='var module:
NodeModule' >module</data-lsp></span><span style="color: #000000">.</span><span
style="color: #267F99"> < data-lsp lsp='(property) NodeJS.Module.exports: any' > exports < /data-
lsp></span><span style="color: #000000"> = {</span></div><div class='line'><span
style="color: #000000"> </span> <span style="color: #001080"> <data-lsp lsp='(property) pi:
number' >pi</data-lsp>:</span><span style="color: #000000"> </span><span style="color:
#098658">3.14</span><span style="color: #000000">,</span></div><div class='line'><span
style="color: #000000"> </span><span style="color: #001080"> <data-lsp lsp='(property)
squareTwo: number' >squareTwo</data-lsp>:</span><span style="color: #000000"> </span>
<span style="color: #098658">1.41</span><span style="color: #000000">,</span></div><div</pre>
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) phi: number' >phi</data-lsp>:</span><span style="color: #000000"> </span>
<span style="color: #098658">1.61</span><span style="color: #000000">,</span></div><div</pre>
class='line'><span style="color: #000000"> </span><span style="color: #001080"> <data-lsp
lsp='(property) absolute: (num: number) => number' >absolute</data-lsp></span><span
```

```
style="color: #000000">,</span> </div> <div class='line'> <span style="color: #000000">};  
    </span> </div> </code> <a class='playground-link'  
    href='https://www.typescriptlang.org/play/#code/PQgEB4CcFMDNpgOwMbVAFwJ4AdoGcBeAlkQHsATa  
    </div>
```

Then these files can be imported via a require statement:

Or you can simplify a bit using the destructuring feature in JavaScript:

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #0000FF"> const </ span> < span style="color: #000000"> { </span> < span style="color: #0070C1"> < data-lsp lsp='const squareTwo: any' > squareTwo</data-lsp> </span> < span style="color: #000000"> } = </span> < span style="color: #795E26"> < data-lsp lsp='var require: NodeRequire&amp;#13;(id: string) => any' > require</data-lsp> </span> < span style="color: #000000"> (</span> < span style="color: #001080"> < data-lsp lsp='color: #000000"> (</span> < div > class='line'> < span style="color: #001080"> < data-lsp lsp='const squareTwo: any' style='border-bottom: solid 2px lightgrey;'> squareTwo</data-lsp> </span> < span style="color: #000000">;</span> < /div> < div class='arrow'> </div> const squareTwo: any </span> < /code> < a class='playground-link' href='https://www.typescriptlang.org/play/#code/PTAEAEFsHsBMFcA2BTAXKAxtSMB2ArAZwCgQlAzASx' KAADD7CLPCCZu6gAFSgALQAjADcAaBxCUkuuQC+xMQwCCicyAAectCCPKBKfnlylOgAzJyZACwANHmE < /div>
```

CommonJS and ES Modules interop

There is a mis-match in features between CommonJS and ES Module because ES Modules only support having the default export as an object, and never as a function. TypeScript has a compiler

TypeScript's Module Resolution Options

Module resolution is the process of taking a string from the import or require statement, and determining what file that string refers to.

TypeScript includes two resolution strategies: Classic and Node. Classic, the default when the compiler flag module is not commonjs, is included for backwards compatibility. The Node strategy replicates how Node.js works in CommonJS mode, with additional checks for .ts and .d.ts.

There are many TSConfig flags which influence the module strategy within TypeScript: moduleResolution, baseUrl, paths, rootDirs.

For the full details on how these strategies work, you can consult the Module Resolution.

TypeScript's Module Output Options

There are two options which affect the emitted JavaScript output:

- <u>target</u> which determines which JS features are downleveled (converted to run in older JavaScript runtimes) and which are left intact
- module which determines what code is used for modules to interact with each other

Which target you use is determined by the features available in the JavaScript runtime you expect to run the TypeScript code in. That could be: the oldest web browser you support, the lowest version of Node.js you expect to run on or could come from unique constraints from your runtime - like Electron for example.

All communication between modules happens via a module loader, the compiler flag <u>module</u> determines which one is used. At runtime the module loader is responsible for locating and executing all dependencies of a module before executing it.

For example, here is a TypeScript file using ES Modules syntax, showcasing a few different options for module:

< div class='code-container'> < code> < div class='line'> < span style="color: #AF00DB"> import < span style="color: #000000"> { < span style="color: #001080"> < data-lsp lsp='(alias) const valueOfPi: 3.142&#13;import valueOfPi' > valueOfPi < / data-lsp> < / span> < span style="color: #000000"> } < span style="color: #AF00DB"> from < / span> < span style="color: #000000"> < span style="color: #A31515"> "./constants.js" < / span> < span</pre>

ES2020

```
 < div class='code-container'> < code> < div class='line'> < span style="color: #AF00DB"> import </ span> < span style="color: #000000"> { </span> < span style="color: #001080"> valueOfPi</span> < span style="color: #000000"> } </span> < span style="color: #AF00DB"> from </span> < span style="color: #000000"> ; </span> < span style="color: #AF00DB"> from </span> < span style="color: #AF00DB"> inport </span> < span style="color: #AF00DB"> inport </span> < span style="color: #AF00DB"> export </span> < span style="color: #000000"> < span> < span style="color: #000000"> < span> < span style="color: #000000"> < span> <
```

CommonJS

```

</div>
```

Note that ES2020 is effectively the same as the original index.ts.

You can see all of the available options and what their emitted JavaScript code looks like in the <u>TSConfig Reference for module</u>.

TypeScript namespaces

TypeScript has its own module format called namespaces which pre-dates the ES Modules standard. This syntax has a lot of useful features for creating complex definition files, and still sees active use in DefinitelyTyped. While not deprecated, the majority of the features in namespaces exist in ES Modules and we recommend you use that to align with JavaScript's direction. You can learn more about namespaces in the namespaces reference page.
